INDEX TO BRITISH MEDICAL JOURNAL

THE JOURNAL OF THE BRITISH MEDICAL ASSOCIATION

NORMAN GERALD HORNER, M.D., F.R.C.P.

Assisted by

HUGH CLEGG, M.B., M.R.C.P.

VOLUME I 1941

JANUARY TO JUNE

Published at the Office of the British Medical Association, Tavistock Square. London, W.C.1, and Printed by Fisher, Knight & Co., Ltd., Gainsborough Press. St. Albans

INDEX TO VOLUME I FOR 1941

READERS in search of a particular subject will find it useful to bear in mind that the references are in several cases distributed under two or more separate headings—for example, Brain and Cerebral; Heart and Cardiac; Liver and Hepatic; Renal and Kidney; Cancer and Carcinoma; Child and Infant; Goitre and Thyroid. Subjects dealt with under various main headings in the JOURNAL have been set out in alphabetical order under their respective headings—for example, "Annotations," "Correspondence," "Leading Articles," "Obituary," "Reviews," etc. Original Articles are indicated by the letter (O).

A

Abdominal diseases, review of book on, 405
—— hyperæsthesia in Army dyspeptics (W. G Mills), 315 (O); correspondence on, 415
—— operations, review of book on, 819
—— pain, acute, after opium medication, 461, 659, 763, 870, 952
ABEL, Lawrence: Rectal carcinoma, 983
ABERCROMBIE, R. G.: Herpes zoster with muscular paralysis and disturbance of sensation, 778
ABRAHAMS, Sir Adolphe: Effort syndrome, 681
Abscess of medulla oblongata and chronic pulmonary tuberculosis (H. B. Norman), 403
Abscesses, pelvic: diagnosis and treatment (H Dodd), 667 (O)
Absorbers, to-and-fro, cut-outs for, 17
Acacia for nephrotic syndrome, 758
Academy, Royal, of Medicine in Ireland. Lower uterine segment, 165—Serum treatment of diphtheria, 374—Adreno-cortical syndrome, 454—Urinary antikepsis, 642—Death after delivery, 681
Accidents, road: Increase in, 387—How are they caused? 469—Doctor commended for brave conduct, 916
Acheson, Fleet Surg. Johnston Hamilton, obituary notice of, 949
Acrocephaly, review of book on, 443
Actinotherapy, review of book on, 713
ADAM, George: Treatment of burns, 603
—— W. B.: Effect of canning, 638
Adams, John James, obituary notice of, 223
Addison's disease, grafting of adrenal gland in (F Katz and F. Mainzer), 617 (O); correspondence on, 658, 730, 798, 870
Adenoma, pituitary, ocular palsy in, 823
Adenopathy, histological specimens in, 169
Adie's syndrome, 58, 99, 138, 175, 218
Adrenal gland, grafting of, in Addison's disease (F. Katz and F. Mainzer), 617 (O); correspondence on, 658, 730, 798, 870
Adrenaline: In asthma, 65, 255—In shock and fever, 578
Adreno-cortical syndrome, 454
Advertisements, medical, by post, 544
Africa: Hospitals for British Forces in Middle East, 96—Leprosy research, committee on, 737—Map of North-East, 578
Age and service, 138
Aged, care of, review of book on, 712
Agglutinin titres of pooled sera, 729
AGNEW, P. W. A.: Treatment of psoriasis, 348
Agranulocytosis: After sulphapyridine, 456, 495—In infant (H. C. Barlow), 669 (O)
Ahern, Lieut.-Col. Michael David, obituary notice of, 835
AINSWORTH, R. M.: Treatment of injuries of fingers, 987
Air disinfection, methods of, 675, 798
—— Force. *See* Services
—— pilots, fitness of, 676

AIR-RAID PRECAUTIONS:
A.R.P. Progress: February issue, 528
Black-out, surgery hours during, 35
Blast. *See* General Index
Blinded civilians, 251, 387—Help for, 658
Bombing and planning, review of books on, 780
Bristol's experience, 978
Casualties: R.A.M.C. and, 224—Treatment of (M. Ball and G. Ouist), 273 (O); correspondence on, 378, 416, 459, 493, 764—General principles of treatment of (P. H. Mitchiner), 309 (O)—Delay in treatment of, 459, 533—Problems of, 490—Distribution of, 518, 526, 728—Some experience (A. M. M. Payne), 564—Reception and treatment of (J. R. Lees), 584 (O); correspondence on, 685; note on, 721—Rescue and after-care after four days' burial (G. S. Swan), 589 (O)—Renal failure in, 685—Treatment of (S. J. Hoffman), 785
Casualty services, 29—Cardiff's example, 423
Chronic sick in bombed towns, 868, 944, 949, 987
Conference on, 250, 287
Coventry revisited, 832
Crush injuries. *See* General Index

AIR-RAID PRECAUTIONS (*continued*):
Dental unit in Glasgow, 304
Evacuation: Compulsory, of children, 128, 387—War strain in children, 124, 128—Problem of, 336—Notes on children, 914
Eye casualties (D. R. Campbell), 966 (O)
First-aid in air raids, 978
—— parties at scene of incident, 416
—— post: Gas decontamination, 61—Dress rehearsal at, 167—Fixed, 255—Cleansing eyes of gas, 795
Gas. *See* General Index
Glasgow's experience, 992
Glass substitutes and protection from flying glass, 789
Home for mothers and babies, 491, 698
Homeless relief of, 976
London air raids, 30—Some medical aspects (V. Z. Cope), 523
Medical aspects of, 250
Mobile unit, 35, 728—In action, 30, 99, 173, 255, 458, 604
Nervous effects, obscure, of air raids, 573, 647, 727, 790, 906
Pregnant women in target area, 174
Provincial cities, Lord Horder's visit, 106
Public health considerations (A. Massey), 82 (O)
Reception area: Report of conditions, 207—Doctors transferred to, 346—Medical problems (R. Y. Stones), 370—Overburdened doctors in, 727, 834
Respirator: Special anti-gas, 206—Addition to, 500—And CO, 832
Shelters: Nurses and matrons, 23—Recommendations by Lord Horder's Committee, 24—Hygiene in, 26—Unification of control, 28, 100—Lice in, 29, 142—Problem of, 57, 61, 174, 414—Tuberculosis and, 61, 136, 601—Medical students for, 72—Medical and sanitary services, 142—Welfare work, 143—Prize essays on, 180—Tuberculous persons in, 181—Food in, 203—Feeding survey in London, 205—Germ masks, 224—Posters on health matters, 224—Discussion on, 250, 287—Policy, 381, 459, 637—Conditions in, 387, 424—Cleansing of, 468—Table, 528—Modern troglodytism, 561
Sound detector for rescue work, 658
Spectacles, provision of, 389
Steel helmets for hospital staff, 576
Table shelters, 528
Working of services, 173

AITKEN, Janet: Juvenile rheumatism and "growing pains," 865
ALBEE, Fred H: *Bone Graft Surgery in Disease, Injury and Deformity*, 557
Albinism: observations on two native Seychelles families (E. Christianson), 556; correspondence on, 608
ALCOCK, A. T.: War strain in children, 124
—— N. S: War casualties, 490
—— Stanley C.: Medical Planning Commission, 132
Alcoholism: And crime, 514—Review of book on, 628
ALDIS, Arnold S.: A.R.P. casualties, 378
Alexander, Thomas Hood Wilson, obituary notice of, 734
Aliens: Registration of doctors, 345, 541, 612, 950—Employment of doctors, 695, 735—Doctors in Pioneer Corps, 764—And medical man-power, 801
All-bran and constipation, 252, 390
Allan, James, obituary notice of, 258, 298
—— James Henry, obituary notice of, 948
Allantoin, 406
Allen, Major Arthur James Walter, obituary notice of, 346
—— Clifford: Obscure nervous effects of air raids, 727
—— Edgar van Nuys: *Specialties in Medical Practice*, 2 vols., 197
—— Irene: Nutrition and dental caries in London school children, 44 (O)
—— R. M.: *Microscope*, 198
—— William Taylor Doyle, obituary notice of, 343
Allergy, respiratory, eosinophils in diagnosis of, 411
—— skin, review of book on, 856

ALLISON, P. R.: Acute bronchiolitis in children, 214
Alopecia: anti-alopecia factor, 325
ALSTON, J. M.: Medical Planning Commission, 649
Ambulance service of London, 424
AMIES, C. Russell: Stability of tetanus antitoxin under suboptimal storage conditions, 709 (O)
Amines, biogenic, review of book on, 953
Ammonium chloride tabloids, 672
Amnioplastin: As conjunctival graft (B. B. Law and J. F. Philip), 514—In peripheral nerve injuries (L. Rogers), 557 (O)
Amniotic membrane for cerebral adhesions, 213
Amputations in bed (H. A. Brittain), 192 (O)
—— emergency: M.R.C. memorandum, 788
Anæmia, haemolytic (leading article), 365
Anaerobic infections, chemoprophylaxis of, 332
Anæsthesia: For major dental surgery (W. W. Mushin), 46 (O)—Mechanism of partial rebreathing in (R. L. Wynne), 155 (O)—Review of book on, 197—Convulsions under (H. A. Logan), 450; correspondence on, 607, 697—Premedication for, 593
—— basal: Hexobarbitone soluble, 5
—— dental, nitrous oxide for, 695, 804
—— intravenous, in obstetrics (K. M. Robertson), 815 (O)
—— local, in general surgery, 454
—— pentothal. *See* Pentothal
—— spinal, 213
Anæsthetics, review of book on, 243
Anæsthetists, nurse, 339, 419, 463, 535, 650
Anæsthetist's slide rule, 161
Anatomy, review of books on, 17, 482, 893
ANDERSON, A. B.: Calcium metabolism, 379
—— Cyril A. (and K. MACCOLL): Carbuncle of duodenum, 277
—— J. Barcroft: Adrenaline in shock and fever, 578
—— Sir John: Address to Pharmaceutical Society, 640
—— Robert: Diphtheria incidence, small-pox analogy, 144
—— T. (and K. J. GUTHRIE): Double infection of meninges, 193 (O); correspondence on, 348
ANDREWES, C. H.: Active immunization, 131
ANDREWS, M. C.: Frostbite, 763
Anethaine, 780
Aneurysm, syphilitic thoracic, in young adults (B. Evans), 851 (O)
Angina pectoris, surgical treatment of, 410
Angiospasm, damp beds and, 416
ANGIOLINY, J (and others): *La Thoracoplastie Elective*, 160
Animals, review of book on, 557
Ankle, review of book on, 87

Annotations:
Acacia for nephrotic syndrome, 758
Adie's syndrome, 58
Air disinfection, methods of, 675
—— pilots, fitness of, 676
Alopecia: anti-alopecia factor, 325
Angina pectoris, surgical treatment of, 410
Antiseptics and brain, 937
—— surgical, to avoid, 784
Atrial septal defect, 781
Baby, birth of, film on, 972
Biliary system, post-operative perfusion of, 598
Blood changes *in vitro*, 58
—— clotting, 935
Brain, functional vascular disturbances in, 783
British Medical Journal: Phoenix number, 824
Bronchitis and other infections in war, 783
Brucellosis, epidemic of, 126
Buerger's disease and typhus, 758
Calcium deficiency, effects of, 521
Cancer: Neutrons in treatment of, 447—Caustic paste for, 936
Clinic, Tavistock, 784
College, Royal, of Surgeons of England, destruction at, 860
Council, Empire Rheumatism, 166
—— London County: Reorganization in public health department, 367
Cross-infection in wards, 247
Cysticercosis, 896
Dental caries in children, 446

SUPPLEMENT

containing

War Notices

Notes on the Work of the Association

National Health Insurance Proceedings

General Medical Council

Postgraduate News

Meetings of Branches and Divisions

Service Appointments

Correspondence, etc.

VOLUME I 1941

Published at the Office of the British Medical Association, Tavistock Square, London, W.C.1, and
Printed by Fisher, Knight & Co., Ltd., Gainsborough Press, St. Albans

Annotations (*continued*):
Dermatomyositis, 562
Diabetics in wartime, 203
Diphtheria, severe, treatment of, 634
Doctors, oversea, employment of, 93
Drugs, dangerous, traffic in, 59
—— economy of, in wartime, 448
Ductus arteriosus, patent, surgical treatment of infected, 368
Electro-encephalograms of problem children, 936
Enzymes, pancreatic, in blood, 165
Eosinophils in diagnosis of respiratory allergy, 411
Epilepsy, 323
Fever, rheumatic, chemoprophylaxis of, 973
Friedländer lung infections, 369
Frost-bite, treatment of, 21
Fund, Royal Medical Benevolent, 937
Galactose tolerance in jaundice and thyrotoxicosis, 367
Gas gangrene, treatment of, 166
General paralysis of insane, treatment of, 486
Genetics of hereditary ataxias and spastic paraplegia, 562
Haemorrhage, acute bilateral adrenal, 718
Headache, mechanism of, 323
Heart: Pathology of cardiac pain, 599
Hereditary diseases, variations in age of onset of, 896
High-frequency apparatus, ban on, 23
Histaminase, 324
Honours, New Year, 23
Hormones, adrenal sex, 322
—— and psychiatric disturbances, 822
Hospital war supplies, 409
—— work: "essential service," 824
Hospitals, emergency lighting and power for, 634
Hysterical contracture in war, 717
Iceland, health in, 325
Impetigo, 448
Indexes, half-yearly, 129
Indian hemp, 676
Industrial psychologist, 164
Infertility in male, 285
Influenza, 283
Intranasal immunization, 22
Jaundice after arsphenamine, 59
King's English, 249
Lighting of streets in wartime, 635
Lung: Clinical measure of pulmonary elasticity, 757
Lupus erythematosus, sulphonamides for, 757
Medical Directory, 1941, 23
Medullotrophic and pancreotrophic activity, 488
Meningitis, cerebrospinal, 164
Milk: Wartime researches on, 248—Supply in wartime, 972
Neoarsphenamine and sulphonamides, 92
Neonatal mortality, problem of, 165
Nephritis, acute diffuse, renal function in, 127
New Zealand, tribute from, 448
Nursing, district, in wartime, 369
Oedema, acute pulmonary, 447
Opium, traffic in, 59
Palsy, ocular, in pituitary adenoma, 823
Pencils, indelible, injuries from, 598
Peritoneal irritation and intestinal activity, 248
Phthisis, treatment of, 369
Physical medicine, orthopaedics, and Services, 633
Pituitary extract, posterior, dangers of, in labour, 675
—— and sensitiveness to insulin, 677
Pneumococcus, action of type-specific antibody on, 324
Pneumonia, lesion of pneumococcal lobar, 971
Polish medical school in Edinburgh, 129
Pressure, effect of, on tissues, 92
Psycho-analysis and psychoses, 21
Psychology, comparative, 284
Quislingism, psychology of, 823
Radio waves, short, biological effects of, 410
Radio-activity, artificial, medical uses of, 368
Radium, medical uses of, 520
Retinal vessels, changes in calibre of, 127
Rheumatism, chronic, problem of, 204
Sarcoidosis of Boeck, 92
Scabies and immigration, 782
Schizophrenia, rheumatic cerebral disease in, 676
School: Duration of secondary school life, 487
Schools, control of infection in, 204
Shelters, food in, 203
Society, Royal: New Fellows, 488
Sulphathiazole and sulphadiazine, 409
Sulphonamide compounds, new, 860
Sympathicomimetic drugs in psychoses, 129
Syphilis, bismuth in, 247
Tetanus, treatment of, 20
Thrush, vaginal, treatment of, 93
Thyroxine and milk-fat, 59
Trichiniasis: In England now, 202—Recovery from, 599
Trichomoniasis in males, treatment of, 22
Troglodytism, modern, 561
Tuberculosis: Mortality from, 366—In wartime, 445—Immunization against, 717—In dogs, 897
Urinary antisepsis, 521
U.S.A.: Health unit and liaison officer, 249—Clinical training for British students in, 409—American doctors for Britain, 635—Medical women's gesture, 897
Veins, spinal, and metastases, 284
Ventilation, measuring, 128
Vitamin A deficiency, dark-adaptation tests for, 446
Walk, learning to, 563
War: Strain in evacuated children, 128—Finance, 597
Whooping cough prophylaxis, 522

Annotations (*continued*):
Women, employment of, in industry, 861
Zinc peroxide for war wounds, 285

ANTHONY, Sylvia: *Child's Discovery of Death: Study in Child Psychology*, 123
Antiseptic and brain, 937
—— surgical, and supply of materials, 784
Anuria, fatal, following sulphapyridine in pneumonia (F. R. Fletcher), 242; correspondence on, 338
Anxiety, review of book on, 628
Apparatus, high-frequency, ban on, 23
Appendicitis: Syphilis in causation of, 552—Cause of, 689, 794
—— acute, operation for, 462
AREY, L. B. *Developmental Anatomy*, 4th ed., 893
Argentine: Diphtheria immunization and Credé's method compulsory in Buenos Aires, 118—Doctors and hospitals in, 736
Armstrong, Keridwen St. Valentine, obituary notice of, 259
Army *See* Services
Arsphenamine, jaundice after, 59
ARNOTT, G. M.: Rotary pump in intravenous therapy, 517
Arteries, peripheral, review of book on, 363
Arteriosclerosis, calcium and, 536
—— obliterans, 574
Arthritis, hypoglandular rheumatoid, oestradiol benzoate in (J. A. Murray), 590
Ascorbic acid *See* Vitamin C
ASCROFT, P. B.: Traumatic epilepsy after gunshot wounds of head, 739 (O); leading article on, 781
Aseptic technique, overhauling (leading article), 246
Askanazy, Max, death of, 69, 178
Association, American, for Advancement of Science: Report of meeting published, 499
—— —— Dermatological: Annual meeting, 801
—— —— Medical Conspiracy trial (leading article), 859
—— —— Neurological: President elected, 36
—— —— Psychiatric: President elected, 543
—— of British Chemical Manufacturers: British drug industry, 215
—— —— Empire Leprosy Relief: Annual meeting, 902
—— —— Hospitals: Annual meeting, 641—Comparison between two cities, 983

ASSOCIATION, BRITISH MEDICAL:
Bristol Division: First aid in air raids, 978
Damage to B.M.A. House, 755
Lectures, 73
Luncheon to American visitors, 346
Medical war issues and, 216
North of England Branch: Treatment of gonorrhoea, 958—Dermatology in military practice, 981
Northern Ireland Branch: Joint meetings, 376
Oxford Division: Report of meetings, 593

Association, British Orthopaedic: Annual meeting, 532—Prize, 737—Physical medicine, orthopaedics, and rehabilitation, 791
—— of Clinical Pathologists: Meeting, 168
—— Family Planning: Annual report, 389
—— of Industrial Medical Officers: Employment of women in industry, 861
—— Ling Physical Education: Course, 466, 973—Annual report, 489—Juvenile rheumatism, 865
—— Mental After-Care: Annual meeting, 567
—— Socialist Medical: Socialized medicine, 454
—— Welsh National Memorial: Report, 331
Asthma, adrenaline in, 65, 255
Ataxias, hereditary, and spastic paraplegia, genetics of, 562
Athenaeum, History of Medicine: Hon. members elected, 614
ATKINS, R. R. G.: Shock of ambulance journey, 63
ATKINSON, C. Hewitt: Effort syndrome, 681
—— Henry: *Life Magnificent*, 968
Atom, review of book on, 405
Atwill, Flying Officer John Anthony, death of, 949
AUCHINLECK, Gladys M.: Sulphathiazole snuff for diphtheria carriers, 332
Auld, Alexander Gunn, obituary notice of, 258

AUSTRALIA:
Birth rate, 840
Blood transfusion service in N.S.W., 424
Children's sanitary train, 499
Examination of recruits, 699, 701
Mosquito squad formed, 615
Red Cross Society, 451

AVLRY, Harold: *Gastric and Duodenal Ulcers*, 753

B

Baby, birth of, film on, 972
BACHARACH, A. L.: Nutritional problems, 99—"English disease," 691
Bacteria, dust-borne, reduction of (J. C. Thomas and M. van den Ende), 953 (O); leading article on, 970
Bacteriological investigation of wounds treated by closed-plaster method (J. Orr-Ewing), 877 (O)
Bacteriology, review of book on, 482
Bacteriostatic effect of disinfectants (M. E. MacKay), 747 (O)
BAILEY, Hamilton (editor): *Surgery of Modern Warfare*, Part I, 279—(And R. J. McN. Love): *Short Practice of Surgery*, 5th ed., 591—Adrenal grafts in Addison's disease, 730

PRIDE AND PREJUDICE IN THE TREATMENT OF CANCER*

BY

Sir ALFRED WEBB-JOHNSON, C.B.E., D.S.O., T.D., F.R.C.S., Hon. F.R.A.C.S., Hon. F.A.C.S.

Surgeon to Her Majesty Queen Mary; Vice-President of the Royal College of Surgeons; Surgeon to the Middlesex Hospital

In eighteen hundred and thirty-three William Wood Bradshaw qualified as a Member of the Royal College of Surgeons of England. He practised at Andover and later at Reading, and was well thought of by the Council of our College, for in 1854 he was elected to the Fellowship without examination, under Clause I of the Charter of 1852. According to various biographies Bradshaw was a student at the Middlesex and Westminster Hospitals, but the only record we possess at the Middlesex is a register which shows that in 1840, seven years after his qualification, he was admitted as physician's pupil.

By the time of Bradshaw's entry at the Middlesex Hospital Charles Bell, the founder of the Medical School, had left on his appointment to the chair of surgery in Edinburgh, but in Erasmus Wilson's history of the hospital we read of others who were on the staff. Among them were Thomas Watson, later President of the Royal College of Physicians, and James Moncrieff Arnott, later President of our College and the benefactor who endowed the Arnott Demonstrations. Francis Hawkins, another member of the staff, was Registrar of the Royal College of Physicians, and his brother, Caesar Hawkins, became President of our College. William Macmichael, the author of the delightful *Autobiography of the Gold-headed Cane*, had recently died, but he had awakened renewed interest in the venerable College of Physicians by directing attention to its past history and to the achievements of the famous men who had been connected with it. Among the other surgeons were Herbert Mayo, who had claimed priority over Bell in his work on the spinal nerves, and Alexander Shaw, Bell's brother-in-law, who was later a Member of the Council of the Royal College of Surgeons. During his time at the Middlesex Hospital, therefore, Bradshaw would be deeply imbued with respect and affection for the two Royal Colleges.

Like many another Middlesex man Bradshaw was a man of piety, as shown by his little book, *Thoughts on the Lord's Prayer*. Like many another Middlesex man he was blessed with a devoted wife, who married him in spite of the fact that her first husband, a rich jeweller of Andover, had jealously tried to prevent her marrying another by leaving his money away in case she re-wed. She showed her devotion to Bradshaw by risking this legacy; together, they showed their sound common sense by buying the reversion for a sum down. In her will Mrs. Bradshaw gave further evidence of her regard for her husband by founding in each of the two Royal Colleges a Lecture to perpetuate his name. This combination of wifely devotion with the "sweet" or "elegant simplicity of the three-per-cents" ensures that each year someone shall occupy this position. In the course of time the appointment of Bradshaw Lecturer has become the highest honour in the gift of the President of our College. I very deeply appreciate the confidence shown in me by entrusting me with this honourable task.

My choice of subject was influenced by various considerations. In the first place, even at the time that Bradshaw came to Middlesex a special department for the investigation and treatment of cancer had been established there for nearly half a century. Bradshaw was also a student of Westminster Hospital, and if he were here in spirit to-day he would find his two hospitals among the foremost in the fight against this dread disease. Moreover, Bradshaw was a general practitioner, and it is on the general practitioner that we rely for the recognition of the significance of symptoms which may lead to the early diagnosis of this disease.

My own path has led me into association not only with the Middlesex Hospital, whose special Department for Cancer Research and Treatment dates from 1792, but also with the Christie Hospital in Manchester, which was founded just a century later. To this latter hospital, now combined with the Holt Radium Institute, I have returned several times, and have seen some of the most successful results of the modern treatment of cancer in certain situations.

This is the fourteenth occasion since the Bradshaw Lecture was founded on which cancer has been chosen as the subject for discussion in our College. It is, however, thirty years, or the conventional length of a human generation, since Sir Alfred Pearce Gould attempted a general survey of the problem. He saw grounds for hope in the fact that in many instances malignant tumours had been observed to disappear under radiation treatment. Towards the end of his lecture he exclaimed, "Watchman, what of the night?" It seemed to me that the circumstances of the present time demanded that someone should pay heed to the answer of the watchman in the Book of Isaiah: "The morning cometh, and also the night: if ye will enquire, enquire ye: . . ." An inquiry into the results of treatment was indeed a matter of urgency. Owing to the war many radiotherapy departments have been partly out of commission and the expert staffs depleted. Large numbers of the population have

* The Bradshaw Lecture delivered before the Royal College of Surgeons of England on November 27, 1940.

been dispersed, continuity of treatment interfered with, and the follow-up of patients made difficult and unsatisfactory.

When I embarked upon my inquiry I found an undercurrent of talk—wild uninformed criticism, a tendency to exaggeration of failures and overstatement of successes. Surgeons and radiotherapists were often in disagreement. There was indeed an atmosphere of "pride and prejudice," frequently the result of "first impressions," which, curiously enough, was the title originally chosen by Jane Austen for her novel. If the pendulum has swung too far away from excisional surgery towards radiotherapy, it is well that it should be so stated in the Royal College of Surgeons. If the swing of the pendulum has been justified by results, it is well that the glad tidings should be welcomed in the headquarters of British surgery.

The present position is that in almost every part of the body except the stomach and intestines the treatment of cancer has become a radiosurgical problem. In the case of the stomach and intestines anatomical conditions are about as favourable as they could be for excisional surgery, provided the disease is diagnosed early. In the stomach excellent results are achieved in early cases. In the streptococcal path of the colon success attends the patient surgeon who will walk delicately like Agag, follow in the footsteps of Paul, adopt the ingenious methods of Seton Pringle, or observe the teachings of our newest Honorary Fellow by conforming to the Devine precepts.

X Rays and Radium

The practice of radiotherapy has grown and is growing at a remarkably rapid rate. This is shown by the increasing number of patients who apply for treatment at the radium centres of the Radium Commission and the Medical Research Council. At the Medical Research Council centres the numbers increased from 1,016 in 1930 to 5,698 in 1938, and in the latter year 60% of patients were having radiation treatment alone—the proportion in general hospitals being 45.5% and in special hospitals as high as 75.9%.

Although man has an inveterate instinct not to confide his weight to a branch until he has tested it, yet in radiotherapy we have for years been using weapons about which we still have much to learn. Terrible mistakes have been made, but there was no help for them. The newfound weapons, however dangerous, simply had to be employed on actual patients, even in an experimental way, because the possibilities of their doing good were so immense. It was one of those instances when, as Trotter said, "In matters that really interest him, man cannot support the suspense of judgment which science so often has to enjoin. He is too anxious to feel certain, to have time to know." It was impossible to maintain an attitude of suspended judgment indefinitely in a matter which might mean life or death to so many—all crying for immediate relief.

When the effects of *x* rays and the gamma rays of radium disturbed established ideas it was inevitable that we should become more and more dependent on more and more division of labour. A division of labour is necessary for the advancement of any science—how much more so in the case of a subject like radiation therapy, which touches so many sciences! As Kipling said, "Isn't it likely that the multitude and significance of the revelations heaped upon us within the past few years have made men in self-defence specialize more and more narrowly? Haven't we been driven headlong to abandon our conceptions of life, motion, and matter? And isn't it human that in the upheaval men may have carried off each his own cherished possession and camped beside it—just as refugees do after an earthquake?" (*A Book of Words*—Speech to the Royal Society of Medicine, November, 1928). So it has happened with the physicist and the radiotherapist, with the result that there is a danger of the surgeon's losing touch.

By specialization, however, the knowledge of what radium and *x*-ray treatment will do has steadily increased. But, as the claims of the beneficial effects of radiotherapy have grown, wiser surgeons have asked that decisions should be deferred and judgments suspended until time had shown whether those benefits were lasting. Surgeons would be failing in their duty if they lightly laid aside the knife or restricted the scope of their operations unless and until they were satisfied that reliable substitutes for radical operative treatment had been made available.

Unfortunately some operations for cancer, although crowned with a large measure of success, entail a heavy primary mortality, and in some cases the resulting mutilation is serious. Radiotherapy acts with greater delicacy, for cancer cells are generally more sensitive than normal cells. The limited tolerance of the skin together with the fact that neighbouring parts may be highly sensitive requires that those who are to use these powerful and dangerous weapons must be very thoroughly trained. Mistakes of the past, now being avoided, showed that in unskilled hands much damage could be done by radiation treatment, and that, like other serious undertakings, it is "not to be enterprised, nor taken in hand unadvisedly, lightly, or wantonly . . . but reverently, discreetly, advisedly, and soberly."

Experimental Cancer

Before considering the results of treatment it is well to call to mind the present state of our knowledge, for this is an essential starting-point for further developments. We still do not know the cause of the disease we are striving to cure, but the results of research lead to the conclusion that there may be a combination of three factors in the induction of an experimental cancer. First, there is an inherent susceptibility or lack of resistance in the individual. Secondly, there may be an irritant, or non-essential, factor: one example of this is the characteristic reaction produced in the skin by the application of a chemical carcinogen, and another is the change produced in the breasts of susceptible animals like mice by overstimulation with large doses of natural or synthetic oestrogenic substances. And, thirdly, there may be a virus as a causative agent, and this may or may not be an essential element.

Research on viruses leads to the very meeting-place between animate and inanimate matter—to the threshold of life itself; for some known viruses seem capable of passing from an inanimate crystalline form to an animate existence. Ideas as to the nature of viruses are conflicting. Some observers regard them as extraneous disease-producing entities, while others maintain that viruses are formed from the protoplasm of the animal cell. Some workers doubt the virus theory and maintain that chemical agents may be sufficient by themselves to induce cancer in a susceptible animal. But, in support of a virus factor in cancer, it must be remembered that tumours have been transmitted from one animal to another by means of a cell-free filtrate, and also that there is evidence suggestive of the development of antibodies (neutralizing and agglutinating immune bodies) in the blood of the host, which raises hopes that a way may be found to stimulate the process of natural resistance.

The occurrence of some cases of experimental cancer is definitely associated with external influences. This is made clear by the demonstration that cancer can be

induced almost at will, that the rate of induction by an extraneous carcinogen can be delayed or accelerated, that the incidence of mammary cancer of hormonal origin can be influenced by environment, and that even the incidence of susceptibility can be modified, for it seems to depend more on some factor in the milk received from the mother or foster-mother than on parentage. In experimental cancer many of these causative factors may be brought under control.

The Problem in Man

Passing from mice to men, there are grounds for believing that the incidence of cancer in the human subject may also be governed by an inherent susceptibility or lack of resistance and, possibly, also by a virus. But in addition to these causes, which we cannot at present control, general environmental factors, such as occupation or social conditions, may play some part in the causation, and there is ample evidence that totally extraneous influences affecting the skin or the respiratory, urinary, or alimentary tract are often local non-essential causes. These extraneous influences may be subject to control.

Experimentalists and clinicians, however, are alike faced with the fact that, whatever causes may combine to produce cancer, once the cancerous cell has developed the malignant growth continues, in spite of the withdrawal of any remote non-essential cause. Various lines of research suggest many possible lines of treatment, but in the present state of our knowledge we can only treat the local manifestation of the disease.

We have not the requisite knowledge to guide us in controlling susceptibility or increasing resistance, nor do we know any general treatment which will arrest the disease process when it has begun. By way of prevention we can, however, do much to exclude extraneous influences which may be remote causes, and we can treat local and general conditions which are known to be frequent precursors of cancer. By way of cure we can attack the cancer locally when it is manifest. This can be done by surgical excision, to which there are limits, or by endeavouring to check an otherwise irreversible process by radiation, a method the full possibilities of which have yet to be learned. There is still an enormous amount of research to be done in radiotherapy, but thanks to the physicist we have now a standard unit of dosage, and with the help of the physicist we can direct the rays accurately and determine the exact dose received by the skin, by the tumour, by the surrounding tissues, and by the individual. But the same dose can be varied in many ways—e.g., in intensity, in time spacing, and in the source of radiation. Moreover, in addition to the physical variables we still have to consider the problem of sensitivity and the different effect produced on the same cells according to the activity or otherwise of mitosis, or the state of nutrition of the cells and, possibly, of the individual. There are favourable times and conditions for radiation treatment, and it is anticipated that if it could be spaced so as to attack the tumour always at times of high radiosensitivity, and to avoid times of high radioresistance, better results would be obtained.

Morbid Histology

The importance of the state of cell activity and its relation to treatment and prognosis has awakened renewed interest in the study of morbid histology, which is by no means so closed or finite a subject or so unprofitable a line of research as many have imagined. The relationship between histological appearance and prognosis has been demonstrated in all the squamous-celled carcinomata, in cancer of the breast, cervix uteri, intestines, and rectum. But the histological grading of tumours, based on the extent of differentiation of the cells and the degree of cell activity, in addition to aiding in the assessment of prognosis may help in deciding on the best line of treatment. If a specimen has been obtained for biopsy the pathologist may have to accept not only the task of exact diagnosis but the additional responsibility of sharing in the decision whether the tumour should be excised, or whether surgical intervention may precipitate disaster; or whether it is of the type that is likely to react favourably to radiation. If a specimen removed by radical operation is submitted for an opinion the pathologist, after careful examination of the whole specimen and after histological grading, may have to help to decide not only the prognosis but also whether post-operative radiation is indicated. It is by these and similar exact scientific investigations in the study of each individual case that results of treatment are likely to be improved; for, as Sir James Paget said in 1882 in the first Bradshaw Lecture ever delivered in our College, "Better treatment will follow better diagnosis, and better diagnosis will certainly follow a more exact pathology."

Early Diagnosis

Morbid histology is one of the important aids not only to exact diagnosis but also to early diagnosis, which is essential to success in cancer treatment. The study of histology may help to reveal, as Paget pointed out, "the time and manner of the first appearing in the case of many diseases."

The master key to success in the treatment of cancer is early diagnosis, and the first step towards this is to secure the opportunity to examine the patient. We must therefore endeavour to remove the haunting fear of the disease. Patients must be brought to realize that cancer is curable and thus led to seek advice without delay. The fact that there is an alternative to operative treatment is a help in leading patients to seek advice early, and indeed has already led to this happy result, as the experience of some radium centres proves.

Now that therapeutic apparatus is so complicated, so costly, and so quickly out of date institutional treatment will become more and more necessary. This will help to dispel the atmosphere of secrecy such as prevailed in the case of President Cleveland when, as dramatically related by Keen of Philadelphia, surgeons were smuggled on to the President's yacht lest during the bimetallism crisis in the United States there should be a financial panic if it were known that he had a malignant growth. (W. W. Keen: *The Surgical Operations on President Cleveland in 1893.*)

The next important step to early diagnosis is skill in clinical investigation, and great advances have been made in methods of examination which can help towards this end.

Results of Treatment

I now propose to attempt a survey of my inquiry into the results of treatment. The opinions I have arrived at must be considered as personal ones. At the same time I have attempted to reach them with a full sense of responsibility, for a Bradshaw Lecture may be vested with some authority, and may be taken to represent an *ex cathedra* statement of the present position. I have endeavoured to avoid bias and to hold a brief neither for surgery nor for radiotherapy, but only for the patient.

In assessing results I have confined myself to a study of those achieved in this country, and as a rule have drawn comparisons between the best obtained by surgery and the best obtained by radiation therapy. I have made no attempt to compare the results of different methods of using radiation as a therapeutic agent; for although it is claimed that methods of treatment have been largely stan-

dardized, yet it has to be admitted that ingenuity in inventing techniques has been so prolific that the different combinations of methods of treatment may be called legion, for they are many. In fact, in a recent report of the Radium Commission it was stated that 110 different combinations had been distinguished for the tongue, 53 for the floor of the mouth, 86 for the breast, 56 for the lip, and 66 for the uterine cervix. Truly a bewildering variety! Technique and clinical judgment count for as much in radiotherapy as in surgery.

The introduction of a new radiological method is likely to lead to excessive enthusiasm, but unfortunately this is often damped by the sobering effect of a cold douche of statistics showing results some years afterwards. Although in the last analysis it is numbers that count, statistics are often misleading and are open to abuse. The study of cancer statistics is very difficult, for there has been no uniform system of keeping records or estimating results. Even when statutory and other bodies have collected information they have acted independently and, as if inspired by some imp of mischief, have adopted different methods of arriving at survival rates. For statistical study it is essential to have uniformity of method. But even when cancer statistics are compiled on identical lines they are often not suitable for comparison, for cases may differ in character in different clinics and there is a personal factor in classifying cases into stages or into operable and inoperable. I have attempted, therefore, to compare results statistically only when numbers, conditions, class of case, and other factors could be reduced to a common denominator and a fair comparison be made.

The Skin

Cancer of the skin is essentially a local disease when first manifest, and even in cases of epithelioma the lymphatic glands are not involved as a rule until the disease is far advanced. Over 90% of 800 cases analysed by the Radium Commission had no glandular metastases when first seen. It is interesting to note, however, that a superficial skin cancer, whether basal-celled carcinoma or epithelioma, is often an outward and visible sign of an inward invisible delitescent and unexplained tendency, for it is by no means uncommon for patients with skin cancer, particularly rodent ulcer, to develop carcinoma elsewhere. In the Radium Commission analysis of 2,534 cases of rodent ulcer 2.1% are reported to have had some other form of cancer before, after, or concurrently with the rodent ulcer. Moreover, multiple rodent ulcers were quite common, over 8% of the patients having more than one (Report of Radium Commission, No. 5883, 1938). At the Middlesex Hospital, where careful note has been kept on this point, 32 out of 671 cases of rodent ulcer, or 4.8%, have had cancer elsewhere, excluding epithelioma of the skin.

It is well known that radiation will cure a large proportion of cases of skin cancer. In some respects this knowledge may be regarded as unfortunate, for many cases are sent direct to the radiotherapist and no other form of treatment is seriously considered. Just as in cancer in other situations, however, a case of cancer of the skin requires to be the subject of joint consideration by surgeon and radiologist. Surgical excision is still the treatment of choice in the case of a small primary lesion when removal can be secured without disfigurement or mutilation. It must also be remembered in this connexion that while recurrences of rodent ulcer are always resistant to radium treatment they are more so after radiotherapy than after excision. Surgery should also be resorted to if the response to radiation is disappointing, and often if the disease has already produced a large defect, for then the surgeon should have the opportunity to remove the growth and plan his line of repair before the healing powers of the tissues have been damaged by radiation. In each case careful consideration should be given as to which treatment will be most successful and least exacting. All circumstances should be taken into account—age and general condition of the patient, as well as the local anatomical problem.

The treatment of *naevo-carcinoma* has been disappointing to surgeon and radiotherapist alike. The extreme malignancy of naevo-carcinomata when they occur on skin or mucous membrane is well recognized. For this reason prophylactic operation by wide excision is indicated when a mole is so situated as to be liable to irritation by pressure or friction. Contrary to general belief many of these tumours are radiosensitive, and it is advisable to try the effect of radiation in all cases. Surgical removal still offers the best chance, however, and successful results have been obtained by removing the whole of the lymphatic drainage area at the time of removal of the primary growth.

The Lip

In cancer of the lip a five-year freedom rate of nearly 65% of all cases can be obtained by radiation and of nearly 90% in Stage I cases. This is as good as or better than surgery, and healing is often obtained without loss of substance. The prognosis depends on the size of the lesion, its site, duration, and whether any glands are involved. In the case of a large, deep, infiltrating epithelioma of the lip, when a considerable defect is inevitable, early surgical excision with plastic repair should be seriously considered. Surgical excision should also be employed when it is clear that a case is not responding to radiation treatment. Neck dissection is required for the lymphatic areas, but only if glands are palpable, for it has been found at the Christie Hospital that in 80% of gland-free cases in which the primary lesion can be made to heal no glandular involvement has occurred. (Christie Hospital and Holt Radium Institute—Five-year Statistical Report, 1939.)

Mouth and Throat

Discussion of cancer of the mouth and throat awakens affectionate memories of Wilfred Trotter and will always evoke a tribute of admiration for his work. If another lateral transthyroid pharyngotomy were never performed we should still owe an immense debt to Trotter, not only for the lessons he taught in operative technique but also for his contributions to what Clifford Allbutt called "the pathology of the living."

Trotter's attitude towards the question of surgical or radiation treatment for cancer of the mouth and throat is expressed in the following statement which he made a few months before his death: "It is a harmful misconception that radiotherapy has already wholly superseded primary radical excision of the disease. That it will ultimately do so we all hope, that it has already done so in large part we all know; but this aspiration and this knowledge leave untouched the fact that, at the present time, there are many cases, easily recognized by the experienced, in which primary operative excision offers by far the most substantial hope of cure." (Unpublished discussion at the Conference of the British Empire Cancer Campaign, 1939.)

Oral Cavity

In the oral cavity radiation has in fact largely superseded radical excision in the treatment of the primary lesion. In recent years at the Middlesex Hospital over 60% of these cases have received radiation treatment only.

In cancer of the cheek, the palate, the floor of the mouth, and the fauces the results of radiotherapy justify the drift from surgery. They are as good as those

obtained by excision and are often secured without mutilation or disfigurement.

In this region as well as in the larynx and pharynx and posterior third of the tongue, we must await the outcome of the radium beam therapy research which has been fostered by our College. The results so far are very encouraging, and in some cases remarkable, but they have still to stand the test of time.

The Tongue

In cancer of the tongue there are fairly comparable figures to help us statistically to assess the value of surgery and radiation treatment. The name of Whitehead of Manchester (not Liverpool as stated in the standard work on *Diseases of the Tongue*) naturally comes to mind in the history of surgical treatment in England, and Sir Henry Butlin, one-time President of our College, set a standard of success which it is often stated has never since been reached by surgery. It has also been stated that it is unsurpassed by radiation treatment, but, as will be seen in Table I, this is not borne out by a comparison of Butlin's results with those of the Christie Hospital.

TABLE I.—*Comparative Tables of Results from Operation and Combined Radiation and Operation for Carcinoma of the Tongue*

Evaluation of Sir Henry Butlin's operation results: Lived for from five to twenty-two years free from recurrence.

Stage	No. of Cases Treated	Net Five-year Freedom Rate
I II III	154	43 (27.9%)
IV	0	Inoperable

(*British Medical Journal*, 1909, 1, 1)

Christie Hospital and Holt Radium Institute: Cases treated in 1932 and 1933.

Stage	No. of Cases Treated	Net Five-year Freedom Rate
I	48	26 (54.1%) } = 45.8% } = 30.8%
II	24	7 (29.1%) }
III	58	7 (12%)
IV	21	0 Inoperable
Total	151	40 (26.4%)

(Five-year Statistical Report—Christie Hospital and Holt Radium Institute, 1939.)

The net survival rate in both tables is calculated after deducting the numbers not traced, those dying from intercurrent disease, and those in whom operation was incomplete.

Stage I = small primary growth, not more than 3 cm.—no glands.
" II = primary spread beyond tissue of origin—still no glands.
" III = ditto—but with glands.
" IV = extensive advanced cases—inoperable.

Net freedom rates are not altogether satisfactory, but they are the only comparable figures in this instance. Butlin's general five-year figure, based on cases traced from five to twenty-two years, is 1.5% better than that of the Christie Hospital for all cases treated, but for the operable cases the rate at the Christie Hospital is 3% better than Butlin's, and we must remember the mutilation and disability resulting from extensive operations in this situation. The conclusion I have come to is that, with the exception of small lesions, recurrences, syphilitic tongues, cancer on leucoplakic areas, and lesions involving bone, radiation treatment of the primary tumour and operative removal of the lymphatic area, if and when the glands become palpable, is the treatment which gives the best prospect of cure.

The choice between surgical and radiation treatment in an individual case may depend on various considerations, such as the site and extent of the primary lesion, and also on the histological type of the tumour. Surgery and radiation are equally successful in small lesions, and surgery may often be indicated—for example, in small lesions of the tip and side of the tongue if the organ has not lost any mobility. We have all had experience of complete cure in such cases. I personally recall a case of hemi-glossectomy for early carcinoma of the tongue in which, in 1905, I assisted the late Sir William Thorburn. The patient lived for thirty-two years without recurrence and held many important positions requiring much public speaking.

Butlin performed a block dissection of the neck as a routine in his later cases. The general plan at the Christie Hospital and Holt Radium Institute is to treat the primary lesion by radiation and proceed to block dissection of the neck if glands are palpable. At one time a block dissection was carried out as a routine procedure, but the mortality of the operation is about 10%, and 68% of all gland-free *mouth* cases did not get any glandular involvement within five years, and *about half the gland-free tongue cases were still gland-free* at the end of five years. Cases without palpable glands are therefore watched carefully and at once submitted to operation if any glands become palpable.

(*The conclusion of the lecture will appear in next week's issue.*)

RECTAL HEXOBARBITONE SOLUBLE

A USEFUL FORM OF BASAL ANAESTHESIA

BY

F. K. BOSTON, M.A., B.Ch., D.A.
Honorary Anaesthetist, Radcliffe Infirmary

AND

N. R. JAMES, L.R.C.P.Ed., D.A.
(From the Department of Anaesthetics, University of Oxford)

The use of hexobarbitone soluble (syn. evipan, cyclonal sodium, etc.) per rectum as a *basal* anaesthetic was first described by Gwathmey in 1936. Subsequently Hogan (1938) published a report of 200 cases of rectal hexobarbitone soluble used as a *total* anaesthetic. Apart from these instances the method does not seem to have been employed by many workers. We therefore decided to try out its application as a *basal* anaesthetic, especially in comparison with avertin, to ascertain its field of suitability in general surgery. The following technique has been evolved from experience gained in over 250 administrations in which hexobarbitone soluble was used per rectum as a basal anaesthetic.

Practical Considerations

We have three main routes at our disposal for the administration of a basal anaesthetic: the oral, the intravenous, and the rectal.

Oral.—This is the simplest method of administration, but in practice it has been found to be unreliable owing to unpredictable variations in the rate of absorption.

Intravenous.—This is the most accurate method, as the dosage can be adjusted during administration according to the patient's reactions. It suffers, however, from the fact that the administration must be carried out by the anaesthetist himself, which as a rule limits its use to the anaesthetizing room. The nervous patient thus loses one of the chief advantages of basal anaesthesia—namely, complete oblivion of his journey to the operating theatre. In addition the effect of a drug administered intravenously is more transient than when given by other routes.

Rectal.—The chief advantages of this route are (1) a fairly even rate of absorption, giving rise to a comparatively constant and prolonged level of narcosis, and (2) the ease of adminis-

tration. The method can soon be taught, and entrusted, to any intelligent nurse.

Most drugs used for rectal administration (e.g., paraldehyde, avertin) require the addition of a comparatively large volume of fluid for dilution. The injection of this large volume into the rectum may cause reflex expulsion, especially in children and nervous patients, unless the solution is run in very slowly by an experienced nurse. Even then "accidents" may occur. Ejection is more likely to happen if the patient has not had his rectum emptied by a preliminary enema, which should have been given not less than eight hours previously. Rectal hexobarbitone, on the other hand, is administered in such a small volume of solution (20 to 30 c.cm.) that its rejection is extremely uncommon: we have not yet had a single case in which this has occurred, even in young children. This is of considerable advantage in dealing with emergency operations. Another advantage is that tests for decomposition of the solution are not necessary as with avertin.

Technique and Dosage for Adults

A preliminary enema to clear the rectum is not required. The patient is weighed; if this is not possible a rough estimate is made. We have found the latter procedure to work satisfactorily in practice, as the dosage of rectal hexobarbitone recommended in adults allows quite a wide margin of error with safety (Hogan, 1938). Accuracy is not essential, since an error of 0.5 gramme either way in the total can be allowed with safety in healthy adults. The dosage varies according to whether there has been premedication with atropine only or morphine or omnopon has been given in addition:

(*a*) When atropine is the sole premedication (e.g., 1/100 grain) the patient's actual or estimated weight in pounds is multiplied by 0.02. The result gives the number of grammes of hexobarbitone soluble to be administered in warm tap-water.

(*b*) When there has been premedication with morphine and hyoscine (or atropine) or with omnopon–scopolamine (e.g., morphine 1/6 grain and hyoscine 1/150 grain one and a half hours before operation) the patient's weight in pounds is multiplied by 0.01 to 0.015 according to his type, age, and condition. The result gives the number of grammes of hexobarbitone soluble required. When morphine or omnopon has been given as premedication the basal narcosis produced is more satisfactory and is less likely to be followed by postoperative restlessness.

To prepare the solution the ampoules of hexobarbitone soluble are opened and each gramme is dissolved in roughly 10 c.cm. of warm tap-water. An hour before the operation the patient is turned on to his left side and made as comfortable as possible. A pillow behind him helps to prevent him from rolling on to his back when asleep. He is then told that a "couple of tablespoonfuls" of solution will be introduced into his "back passage," that he will have no difficulty in retaining it, and that it will soon send him to sleep. The solution is placed in a funnel, which is connected direct (as small a dead space as possible) to a suitable size of soft rubber catheter, the end of which is lubricated with vaseline. Any air is expelled by allowing the solution to fill the catheter, which is then pinched one to two inches from the end to be inserted. The catheter is gently inserted two to three inches into the rectum and the solution is allowed to run in *quickly*. A small additional amount of tap-water, say, about 10 c.cm., is run in to clear the catheter, which is removed immediately. The whole procedure takes not more than five minutes. Sleep usually comes on within twenty minutes and lasts for four to five hours. During the period of unconsciousness the patient responds to painful stimuli if the dosage has been correctly estimated. Respiration is quiet but not unduly depressed. The unconscious patient must be watched by the nursing staff and the usual attention paid to the maintenance of a clear airway. If necessary an artificial airway must be introduced. To prevent his tongue falling back it is advisable to keep the patient on his side till he arrives in the anaesthetic room. This position is also desirable after operation until the patient has recovered the control of his own airway. We have no objection to the adoption of this position after any type of operation, including abdominal operations.

Technique and Dosage for Young Children

For children of 10 months and upwards we use atropine alone or combined with a small dose of nepenthe as premedication. The nepenthe is desirable if the child is to have a local anaesthetic. The patient's weight in pounds multiplied by 0.02 gives the required dose in grammes of hexobarbitone soluble. The child must be weighed *accurately*, and the solution, in contradistinction to that in the adult technique, must be made up correctly by means of a 10-c.cm. syringe, which is connected direct to a small soft rubber catheter, no funnel being employed. The catheter is then gently inserted into the rectum for an inch or so, but the injection of the solution is not begun until the child has been soothed and his attention diverted from the procedure. The administrator may then inject the solution cautiously, being ready to stop temporarily if the child shows signs of straining. When the injection has been completed the catheter is cleared by means of a few cubic centimetres of warm tap-water. It is then clamped and left *in situ* until the child is asleep, as immediate withdrawal may cause rejection of the fluid. As in adults, the lateral position must be insisted upon until the child reaches the theatre.

Clinical Application

We have used the method outlined above on more than 250 cases, some of which have been classified as follows to show its varied uses.

Surgical Procedure	Age Limits	No. of Cases	Supplementary Anaesthesia	Comments
Vaginal repair, and colpo-perineorrhaphy	32–66	12	Open ether. N_2O & O_2. C_3H_6 & O_2	Respiratory and circulatory depression in one patient after unnecessary depth with ether
Excision of adenoma of thyroid	30–53	8	N_2O & O_2. C_3H_6 & O_2	Longer recovery period is here a disadvantage
Inguinal herniorrhaphy	1.5/12–56	33	N_2O & O_2. Open ether. Field block	
Partial gastrectomy	28–62	25	N_2O & O_2. C_3H_6 & O_2. Field block with splanchnic block	
Gastro-enterostomy	38–59	13	N_2O & O_2. C_3H_6 & O_2. Field block with splanchnic block	
Amputation of leg ..	50–67	5	C_3H_6 & O_2	All patients with gangrene: four diabetic, one traumatic
Appendicectomy ..	8–68	66	Open ether. Warmed ether. N_2O & O_2. C_3H_6 & O_2. Field block	Respiratory and circulatory depression in one patient after unnecessary depth with ether. A number of emergency cases are included here
Radical amputation of breast	38–62	9	N_2O & O_2	
Mastoidectomy ..	4–42	10	N_2O & O_2. C_3H_6 & O_2	
Change of plaster ..	10–52	26	Nil	One case became restless in theatre and required some N_2O & O_2
Toilet of burns in children	3–12	17	N_2O & O_2 required in some cases	

Advantages and Disadvantages of the Method

Advantages.—(*a*) There is usually complete amnesia of the journey to and from the theatre and for some hours afterwards, even if the patient has had a small dosage and has appeared only drowsy on arrival in the anaesthetic room. (*b*) Less inhalation anaesthetic is required. (*c*) The incidence of post-operative vomiting seems to be less than when inhalation anaesthesia is used alone. (*d*) Compared with avertin, hexobarbitone soluble is easy to prepare and administer and rejection does not occur. (*e*) The method is very suitable for combination with local infiltration and field-block anaesthesia. When injecting a local anaesthetic into a patient under this form of basal narcosis the limbs should first be strapped down, as the patient is liable to move in response to the needle prick. The fact that barbiturates in general protect the patient against toxic effects of local anaesthetics is an additional advantage when using this combination. (*f*) The above advantages, especially ease of preparation, make it suitable for Service patients under war conditions

Disadvantages and Untoward Effects.—The only untoward effects we have observed have been as follows: (*a*) Restlessness in a few patients. This has not been severe and has been easily controlled by the attendant nurse. It rarely occurs if an opiate has been included in the premedication. (*b*) In only two cases has undue respiratory and circulatory depression been seen in patients premedicated with morphine; these were given an unnecessarily deep ether narcosis following a full dose (e.g., 0.2 gramme per pound body weight) of rectal hexobarbitone. Since we have gained more experience in dosage we have not seen this complication. The above patients responded to intravenous coramine and inflation with oxygen. (*c*) The length of the period of post-operative unconsciousness. This might be a disadvantage in certain cases, such as when fluid therapy by mouth is indicated as soon as possible after operation—e.g., partial thyroidectomy, etc.

The contraindications are those which apply to basal anaesthesia in general.

Summary

More than 250 patients undergoing various surgical procedures have been given rectal hexobarbitone as a basal anaesthetic followed by various forms of supplementary anaesthesia. Our experience suggests that the method is a satisfactory and easy way of producing basal narcosis.

THE EFFECT OF POTASSIUM SALTS ON CARDIAC IRREGULARITIES *

BY

L. I. M. CASTLEDEN, M.D., M.R.C.P.

Physician, Redhill County Hospital; late Demonstrator of Clinical Medicine, British Postgraduate Medical School

The use of potassium salts to check attacks of paroxysmal ventricular tachycardia and to prevent the occurrence of auricular and ventricular ectopic beats was reported by Sampson and Anderson (1930). In 5 cases out of 12 they were able to control the arrhythmia. The same workers (1932) later published their observations on 58 further cases, in 50% of which auricular or ventricular ectopic beats or tachycardia were checked for varying periods by an oral dose of a potassium salt of from 1 to 16 grammes. In several of their patients the arrhythmia could be permanently controlled by a maintenance dose of a potassium salt. Five different salts of potassium were used—the chloride, iodide, bromide, citrate, and acetate—all with apparently identical effects.

Extrasystoles after Injection of Adrenaline and of Insulin

The appearance of extrasystoles after an injection of adrenaline is a well-known phenomenon, and when it was shown that this substance causes a fall in the serum potassium level in man (Castleden, 1938; Allott and McArdle, 1938), the possible connexion between these phenomena and the work of Sampson and Anderson seemed worthy of investigation. At the same time the effect of potassium salts was tried upon patients who had spontaneous extrasystoles.

Adrenaline.—Of 18 subjects, aged from 21 to 71 years, who received an injection of 1 mg. of adrenaline hydrochloride intramuscularly 8 produced extrasystoles; but these varied in number per minute and were usually too transient to be useful for testing the effect of potassium in preventing them. In one of these subjects—who fairly regularly had 4 or 5 extrasystoles per minute, beginning at 16 and lasting till 24 minutes, after an injection of either 0.5 or 1 mg. of adrenaline hydrochloride—they were not abolished by an oral dose of 6 grammes of potassium chloride given one hour before they were due. In another, who had about 17 extrasystoles per minute, beginning at 4 and lasting until 29 minutes after receiving 1 mg. of adrenaline hydrochloride, they were reduced to 4 per minute by 6 grammes of potassium chloride orally one hour before they usually appeared.

It was considered that for the experimental production of extrasystoles adrenaline hydrochloride was too inconstant and unreliable a method for proper controls to be obtained.

Insulin.—Insulin by subcutaneous injection, sugar by mouth, or both together have been shown to cause a fall of serum potassium level (Aitken, Allott, Castleden, and Walker, 1937; Allott and McArdle, 1938; Harrop and Benedict, 1924; Kerr, 1928). It was of interest, therefore, when a female diabetic patient, aged 52, who was difficult to stabilize, was found to have attacks of extrasystoles during her periods of hypoglycaemia. When she was stabilized the following experiments were performed:

On May 25, 1938, at 11 a.m., her resting cardiac rate on auscultation was 65 per minute and perfectly regular, no extrasystoles being present. The blood sugar was 90 mg. and the serum potassium 18.2 mg. per 100 c.cm. At 11.30 a.m. she received her usual dose of 15 units of insulin, the meal due at 12 noon being omitted. At 12.25 p.m. a typical hypoglycaemic attack was beginning and there was an average of 10 extrasystoles per minute, counted over a long period. The

* This work was done at the British Postgraduate Medical School during the tenure of a Medical Research Council Fellowship.

blood sugar at this time was 70 mg. and the serum potassium 14.2 mg. per 100 c.cm. Glucose orally relieved the hypoglycaemia, but extrasystoles persisted for some time afterwards.

On May 28 at 11 a.m. the cardiac rate was 64 per minute and regular, no extrasystoles being present. Blood examination showed a sugar content of 112 mg. and a serum potassium level of 18.4 mg. per 100 c.cm. A dose of 6 grammes of potassium chloride was given orally at 11.10 a.m. and the usual dose of insulin at 11.30 a.m., the midday meal being omitted as before. At 12.20 p.m. hypoglycaemic symptoms were present and the apical rate was 75. There were no extrasystoles. Blood sugar at this time was 66 mg. and the serum potassium 20.1 mg. per 100 c.cm. Glucose by mouth relieved the hypoglycaemia, and no extrasystoles were observed up to the end of the experiment at 2 p.m., when the blood sugar was 170 mg. and the serum potassium 23.6 mg. per 100 c.cm.

Spontaneous Extrasystoles

Case 1.—A man aged 83 was admitted in cardiac failure due to hypertensive heart disease and auricular fibrillation, with completely irregular rhythm. An electrocardiogram showed auricular fibrillation with a slow ventricular rate and many ventricular extrasystoles. A dose of 6 grammes of potassium chloride was given orally, and 32 minutes later the ventricular extrasystoles were abolished. Four hours after the administration of the potassium chloride the extrasystoles began to return.

Case 2.—A woman aged 61, admitted with hypertension and cardiac failure, was observed to have continuous pulsus

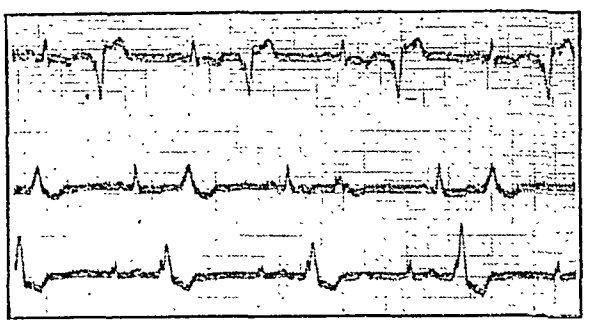

FIG. 1.—Electrocardiogram of Case 2 before administration of potassium chloride.

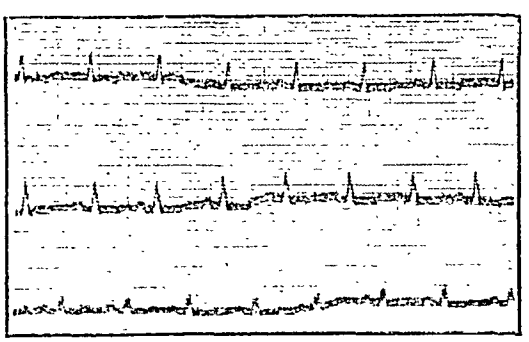

FIG. 2.—Electrocardiogram of Case 2 after administration of potassium chloride.

bigeminus a few days after admission. This was at first thought to be due to digitalis intoxication, but after omission of this drug the coupling continued (Fig. 1). A dose of 2 grammes of potassium chloride orally had no effect on this rhythm. A dose of 4 grammes reduced the number of extrasystoles from 48 to 20 per minute, and 6 grammes orally abolished them entirely for two hours (Fig. 2).

Case 3.—A woman aged 56, suffering from rheumatoid arthritis, regularly had 13 to 18 extrasystoles per minute. A dose of 3 grammes of potassium chloride orally abolished these, the effect being observable at 25 and lasting till 175 minutes after the dose. On another occasion the number of extrasystoles was 13 per minute and the serum potassium was 21.1 mg. per 100 c.cm. A dose of 4 grammes of potassium chloride orally raised the serum potassium to 28.1 mg. per 100 c.cm. in 48 minutes and abolished the extrasystoles from 18 minutes after it was taken until 2¼ hours later, when there were 3 extrasystoles per minute and the serum potassium had fallen to 22 mg. per 100 c.cm.

Case 4.—A man aged 43, suffering from dyspepsia, was observed to have 10 to 12 extrasystoles per minute constantly. The serum potassium was found to be 16.5 mg. per 100 c.cm., and 6 grammes of potassium chloride was given orally. The number of extrasystoles progressively diminished until one hour after the dose none was observed. At this point the serum potassium had risen to 23 mg. per 100 c.cm. The effect of the potassium persisted for a further two hours, when extrasystoles began to make their appearance again, and the serum potassium level had fallen to 19.5 mg. per 100 c.cm. This man was then put upon a maintenance dose of 2 grammes (30 grains) of potassium chloride three times a day orally, and during the time he was taking this he had no extrasystoles.

Extrasystoles after Ephedrine

An asthmatic woman aged 29 was found to have extrasystoles on the day following a dose of 1/2 grain of ephedrine by mouth, given during the preceding night for an attack. She stated that this drug gave her palpitations, her own doctor having advised its discontinuance for this reason. A first dose of 1/2 grain by mouth was found to cause a fall of serum potassium from 17.7 mg. per 100 c.cm. before the dose to 15.8 mg. four hours after, no extrasystoles occurring during that period. A further test dose of 1 grain by mouth caused the serum potassium to fall from 18.2 mg. to 14.2 mg. per 100 c.cm. in two hours. There were again no extrasystoles, but the patient complained of consciousness of the heart's action. On examination the heart was overacting; the resting rate had increased by 10 beats per minute, and the pulse pressure by 15 mm. Hg, chiefly by a fall of diastolic pressure.

One subject who refused to have samples of blood taken consented to an intramuscular injection of 1/4 grain of ephedrine, following which he had a pronounced elevation of systolic blood pressure with numerous extrasystoles for two hours. These observations make it all the more unfortunate that his serum potassium could not be estimated.

A further series of tests to determine the effect of ephedrine on the serum potassium level was therefore made. It was found that this substance, in contrast to adrenaline (Castleden, 1938), did not always produce a fall in the serum potassium level. It was also found to be more inconstant than adrenaline in the production of extrasystoles, and sometimes failed to produce the rise of blood pressure which is to some degree a constant effect of adrenaline (see accompanying table).

Discussion

Ever since the classical experiments of Ringer (1882, 1883) it has been realized that the presence of potassium

Table showing Effect of Ephedrine on the Serum Potassium Level

Experiment	Age of Subject	Resting Serum K (mg. per 100 c.cm.)	Dose of Ephedrine in grains	Serum Potassium Levels in mg. per 100 c.cm. at the Following Hours after Ephedrine								Remarks
				½	¾	1	1	1½	2	3	4	
1	29	17.7	0.5 (O)								15.8	No E.S. No change in B.P.
2	29	18.2	1.0 (O)						11.2			No E.S. Slight rise of B.P.
3	45	20.6	0.5 (O)						18.6		20.6	No E.S. No change of B.P.
4	38	17.3	0.5 (I.M.)		20.7		17.3	19.3	18.4	20.8		No E.S. Pallor and marked rise of B.P.
5	30	16.5	0.5 (I.M.)	17.6	17.1	17.6	20.3					No E.S. No change of B.P.

O=Oral I.M.=Intramuscular E.S.=Extrasystoles.

was necessary to the proper functioning of heart muscle. Ringer showed that full relaxation of the heart muscle in diastole did not occur in the absence of potassium, that potassium increased the latent period of the response to stimuli and lengthened the refractory period, and that an excess of it caused a cessation of the heart-beat in diastole. He further showed that all these actions were the opposite of those produced by calcium, a proper balance between this element and potassium being necessary to the normal functioning of heart muscle.

Since then a great deal of experimental animal work has been done on this subject. Gross (1903) found that calcium increased the strength of cardiac contraction, lengthened systole, and decreased the sino-auricular nodal rate. Von Egmond (1913) showed that calcium increased the auriculo-ventricular conduction time and tended to produce spontaneous auricular and ventricular ectopic beats. Excess of calcium has also produced auricular and ventricular fibrillation (Rothberger and Winterberg, 1911; Hofmann, 1915).

Gross (1903) and Hofmann (1915) showed that potassium diminished the strength of cardiac contraction, shortened systole, increased the sino-auricular nodal rate, and lengthened the auriculo-ventricular conduction time in animals. Hering (1903) was able to stop paroxysmal ventricular tachycardia and ventricular fibrillation by the intravenous injection of potassium salts in the dog, and many other examples of the arrest of auricular or ventricular ectopic rhythm by this means are on record (Rothberger and Winterberg, 1911; D'Halluin, 1926; Wiggers, 1930). These workers and Norn (1929) have shown that the chloride, citrate, and acetate of potassium can be taken by man in oral doses of 1 to 15 grammes without danger, and that 10 c.cm. of a 1% solution could be given intravenously without ill effect. They have also shown that potassium salts are fairly rapidly absorbed from the alimentary canal, the maximum rise of serum potassium being observed in from three-quarters of an hour to two hours after ingestion, which agrees with our own observations (Aitken *et al.*, 1937). Potassium salts are rapidly excreted except in renal failure, which seems to be the only contraindication to their use (Smillie, 1915; Wilkins and Kramer, 1923; Rabinowitch, 1925; Cushny, 1917).

The cases recorded in this paper confirm the work of Sampson and Anderson, which seems to have attracted little attention in this country, and the work on insulin, adrenaline, and ephedrine indicates that it is possibly the fall of serum potassium which causes the well-known phenomenon of extrasystoles to appear after their therapeutic use and suggests that the oral administration of a potassium salt would sometimes eliminate this action where it occurs.

It is worthy of note that the initial level of serum potassium is not always low in patients with spontaneous extrasystoles and that the dose required to establish normal rhythm varies from patient to patient. There would seem to be four possible ways in which potassium might act in abolishing arrhythmia:

1. By the mechanism discovered by Ringer—that is, by depression of the conductivity and prolongation of the refractory period of heart muscle.

2. By replacement of the deficient potassium which has been postulated to be present in the heart muscle in some of these patients (Sampson and Anderson, 1930; Harrison, Pilcher, and Ewing, 1930).

3. By altering the hydrogen-ion concentration of the blood—an aspect of the problem which it is proposed to investigate.

4. By altering the ratio between the potassium and calcium or the potassium and sodium. This would seem to be supported by the facts that potassium chloride has been shown experimentally to produce cardiac irregularity (Wiggers, 1930; Report of Strangeway Laboratory, 1926) and that in three of Sampson and Anderson's cases a paradoxical effect was noticed after ingestion of potassium salts. In two of these there was an increase in the number of extrasystoles, and in one paroxysmal ventricular tachycardia was initiated. The oral administration of 4 grammes of potassium chloride three times a day increased the number of attacks of paroxysmal tachycardia in a patient of Dr. Paul Wood's (personal communication).

Summary and Conclusions

The administration of potassium salts caused the disappearance of extrasystoles in one case in which they were associated with insulin hypoglycaemia and in four in which they were spontaneous.

In three of these five cases the level of potassium in the serum was estimated and the disappearance of the extrasystoles was associated with a rise in potassium level.

Attempts to produce extrasystoles by the administration of ephedrine were not successful. In contrast with insulin and adrenaline, ephedrine does not produce consistently a fall in the serum potassium.

Potassium salts have been reported to produce cardiac irregularities in experimental animals and to increase the incidence of extrasystoles and paroxysmal tachycardia in some patients, so that their action in suppressing extrasystoles cannot be utilized with confidence in the treatment of patients until further work has clarified the mechanism of these effects.

My thanks are due to the Chief Medical Officer of the London County Council and to Mr. J. N. Deacon, medical superintendent of Redhill Hospital, for their consent to the publication of this paper.

J. Mathieu (*Thèse de Paris*, 1940, No. 297), who records twenty-one cases in patients aged from 25 to 45, states that the pseudo-ulcerative form of duodenitis is assuming an increasing importance among duodenal affections. The condition is to be explained by inflammation in the ileo-caecal region, especially chronic appendicitis. Although the symptoms closely resemble those of duodenal ulcer, the correct diagnosis can be made by radiological examination. Treatment should start as soon as possible and should consist in removal of the chronically inflamed appendix and ileo-caecal adhesions. In cases where the symptoms persist, gastrectomy or duodeno-jejunostomy should be performed.

BROMIDE THERAPY AND INTOXICATION

BY

FRANCIS PILKINGTON, M.B., M.R.C.P., D.P.M.

Deputy Medical Superintendent, Warwick County Mental Hospital; Honorary Psychiatrist to the Coventry and Warwickshire Hospital and to the Warneford Hospital, Leamington Spa

In these days of "the war of nerves," especially in the present phase of nightly air raids, many people of "nervous" temperament suffer from an increase in their feelings of anxiety: moreover, exceptional nervous strain may produce symptoms of anxiety (such as irritability, tenseness, physical and mental restlessness, or insomnia) in individuals not constitutionally anxious. The most widely used drug in the treatment of such cases is one of the bromide salts, and there is no doubt that bromides when properly administered are extremely effective for those "nervous" cases in which anxiety in one or other of its forms is the outstanding feature, and especially so when there is reason to believe that *external* events (in contrast to intrapsychic conflicts) are causing it.

Finding the Optimum Dose

It is often not realized, however, that there are considerable variations in the dosage required to produce the greatest therapeutic effect, and that it is necessary, when once the optimum dose is discovered, to maintain it, usually for several weeks. It may be added that a gradual lowering of the dose at the end of treatment is sometimes better than a sudden cessation. Now this variability in the optimum dose depends on two factors: first, the rate of excretion of the drug: and, secondly, the personal factor whereby the optimum concentration of bromide in the blood can vary widely in different individuals. As an example of this second factor a blood bromide of 150 mg. per 100 c.cm. may be the optimum level in Patient A, while 50 mg. is best for Patient B. Moreover, Patient A might be completely unaffected if his blood bromide was kept at 50 mg., whereas Patient B if allowed to have 150 mg. per 100 c.cm. of bromide in his blood for many days might develop an acute toxic delirium. It is therefore useless, when giving bromides, to aim at reaching any definite level in the blood, and it is impossible to state what is a definite toxic threshold. On the whole, however, levels of under 100 mg. per 100 c.cm. may usually be considered safe, while in the range from 100 to 200 mg. toxic symptoms are likely to appear in certain subjects, and levels of over 200 mg. more often than not produce such symptoms. But the personal factor must never be forgotten since levels of over 350 mg. have been recorded without symptoms having been observed. In short, when considering bromides, "one man's meat is another man's poison."

The rate of excretion depends chiefly on the efficiency of the kidneys and the daily fluid and sodium chloride intake. It should be remembered that bromide acts by replacing the chlorides in the body, and the greater the consumption of salt in the diet the more rapid the excretion of bromide. Thus, if 50 grammes of bromide is given to a person who is on a low salt diet and has a small fluid intake the blood bromide at the end of twenty-four hours will be appreciably higher than when the same amount of bromide is given to someone having a greater salt-fluid intake. Patients with arteriosclerosis or cardiac or renal disease are slow excretors of bromide, and so are apt quickly to accumulate toxic concentrations of the drug, and, in general, elderly patients—with or without obvious arteriosclerosis—are liable to become intoxicated even with a low concentration.

Need for Careful Clinical Observation

The above considerations should make it clear that medication with bromides calls for careful clinical observation and control if real success is to be achieved. Doses must be large enough to be effective yet not so large as to intoxicate. It is not suggested that routine blood-bromide estimations should be made, though the test is extremely valuable in some cases—e.g., in giving guidance as to whether a swaying gait is due to an increase in hysterical symptoms or an early intoxication, and in such cases as are presently recorded. Above all, in our efforts to give bromides scientifically we must not forget that our patients are morbidly over-anxious and that they are asking for reassurance, though perhaps many of them are too anxious to ask out loud. In nine out of ten cases with prominent anxiety symptoms one or other of two recurring dreads is worrying the patient: it is either "Shall I lose my reason?" or "Shall I suddenly drop down dead?" Yet it is surprising how rarely a patient will dare to disclose either of them spontaneously. In short, the individual must be treated with psychological understanding, and when the symptoms have been clearly produced by environmental stress the advantages and disadvantages of sending the patient away for a time must be carefully considered.

When bromide treatment has been decided on, a useful initial dose is 10 grains of one or other of the salts thrice daily. On the other hand young adults showing acute symptoms of anxiety can be given double the above dose—i.e., 20 grains thrice daily. In either case the patient should be seen at the end of a week, as by that time there should already be some improvement if the dose is adequate. (Renewed psychological help will also be demanded by that time.) If there is no improvement the dose can be increased by about 50%, but not more than 90 grains daily should ever be given. On the whole those with intense symptoms need larger doses than mild cases, but the drug should always be prescribed with care for patients over 50. After two weeks mild symptoms of intoxication can begin, and should therefore be watched for. The common symptoms are complaints of tiredness, weakness, "dopeyness" or "drunkenness," inability to concentrate through mental sluggishness, failing memory, loss of appetite, and broken uneasy sleep. Some of these symptoms, of course, may have been complained of before the bromide treatment was started, but if the original symptoms of anxiety first recede and then some of the symptoms common to anxiety and intoxication develop a few weeks later, one's suspicions should be aroused.

Treatment of Bromide Intoxication

As the subject of bromide intoxication was ventilated rather freely a few years ago (Barbour, Pilkington, and Sargant, 1936), it is not proposed to dilate on the different mental and physical conditions that may be produced. It will suffice to say that the more severe intoxications are typical toxic-delirious states with confusion and visual hallucinations, while in the most severe cases coma is produced which in rare instances is fatal. It should be emphasized in passing that the presence of an acneiform skin eruption which the older textbooks used to delight in mentioning is the exception rather than the rule (Craven, 1933; Sharpe, 1934). The treatment of bromide intoxication when established or suspected is a simple procedure. The bromide is immediately stopped and large quantities of bland fluids are given. Sodium chloride is also given—30 grains four-hourly. As a precautionary measure while administering long courses of bromide the drug should be stopped for about ten days every few weeks: it is sometimes wise to give, in addition, a salt mixture during these "rest periods."

Bromide is of course one of the most widely used of all drugs, yet it is surprising how often patients with anxiety states are seen in consultation who have never had any, or at any rate not more than an odd bottle, which is practically useless. Nevertheless, in every few months of psychiatric practice a serious case of bromide intoxication crops up. The following two cases are reported, not to discourage the use of a valuable drug, but because they are of special interest. Case I was a patient practically moribund during the peak of her intoxication; it illustrates the danger to life from what is sometimes considered a harmless drug.

Case I

The patient, a woman aged 58, was first seen on December 19, 1939. Until two months previously she had always been healthy and had had no illness of any kind. She is a happily married woman, cheerful and well adjusted, and comes of a healthy family.

In October, 1939, she developed a right facial herpes zoster, the area supplied by the ophthalmic division of the fifth nerve being chiefly affected. The eruption became infected and she developed erysipelas. This quickly subsided, but she became drowsy and a diagnosis of meningitis was considered. She was then given a blood transfusion, but without noticeable improvement. For the next three weeks she became increasingly irritable, tearful, resentful, and paranoid. She then became semi-comatose and frequently screamed and moaned. When examined on December 19 in a general hospital she was extremely drowsy, but could be roused for short intervals. It was apparent that she was very confused and completely disoriented. The only constant feature of her confused state was an idea that the nurses were laughing at her. Physically her general condition was poor, and she looked very toxic and dehydrated. There was no rash. A diagnosis of a toxic-confusional state was made, and bromide intoxication was suspected because she had a tendency to herpes labialis, though her husband thought she had not been having any bromides. A sample of blood was then examined, and bromide content was found to be 300 mg. per 100 c.cm.

When next seen, on December 22, her general condition was much worse. There had been difficulty in giving her the large quantities of fluids ordered and she had consequently become even more toxic and dehydrated. Her temperature was 100° and she had a thready pulse, the rate being between 120 and 130. She was quite unconscious but very restless. She was moved to the Warwickshire and Coventry Mental Hospital the same afternoon and rectal salines were started immediately. She became so restless that repeated small injections of morphine (combined with coramine) were given during the first twenty-four hours. The main eliminative treatment was with large quantities of bland fluids, and during the three and a half days immediately following her transfer she received at least 584 oz.—an average of 167 oz. (i.e., more than 8 pints) a day. She at once began to improve, and by December 27 was conscious enough to be able to describe visual hallucinations, the occurrence of which is so common in toxic mental states. On December 29 her blood bromide was down to 250 mg., and by January 3, 1940, to 175 mg., per 100 c.cm. By the beginning of January she was able to walk a few steps unaided, and, apart from an anaesthetic right cornea and diminished appreciation to pin-pricks in the 5^1 and 5^2 areas, there were no physical signs. She was almost clear mentally and had good insight. Her blood bromide when last examined on January 23 was 125 mg. Other tests done at this time included urea clearance, which gave 70% of normal function; C.S.F. examination, which was normal in all respects (bromide 125 mg.); and the Wassermann, which was negative.

By the time she was discharged on January 31 she had completely recovered physically and mentally, and has remained well since except for occasional pain around the right eye.

Case II is of interest because it was produced accidentally by me while the patient was in hospital, in spite of precautions against intoxication having been taken; it illustrates the degree of vigilance necessary. The chief clinical interest of the case, however, was the greatly disordered carbohydrate metabolism which was temporarily produced by the toxaemia and which at first confused the diagnosis. Eric Holmes (1939) in a critical survey of the literature of abnormal carbohydrate metabolism states that it is well known that toxaemia produced by bacteria, and also by substances such as chloroform and phosphorus can have drastic effects on carbohydrate metabolism, and Elkeles and Heimann (1927, 1928) found that 40 grammes of fructose given to diphtheritic patients sometimes caused hyperglycaemia and glycosuria. Such abnormality of metabolism occurring as the result of bromide toxaemia has not been previously reported so far as I know, though Dr. R. D. Lawrence informs me that he has seen almost the same with morphine poisoning.

Case II

A 64-year-old widow was admitted to hospital in April, 1939, in a depressed and agitated condition. She also expressed some depressive delusions; but there were no hallucinations, nor was there any evidence of intellectual deterioration. Physically she was in good health and there were no signs of disease. The blood pressure was within normal limits and no arteriosclerosis was found. Urine was normal and contained no sugar; the Wassermann reaction was negative and the blood count normal. Previously she had been a cheerful and capable woman and had always been healthy. She had been a hotel manageress, and when she retired in 1937 she at once regretted it. By the end of that year she had become agitated and depressed, in which state she remained without important change till her admission to hospital.

A few weeks' treatment, however, resulted in considerable improvement, and soon she started to lead an active life in hospital. Nevertheless on September 6, 1939, as she was still over-anxious, she was given a bromide mixture (ammonium bromide, 10 grains thrice daily), which was continued until October 18. A slight sedative effect was obtained, but there were no signs of intoxication. The mixture was then withheld for ten days purely as a precautionary measure, it being my practice to do this when giving bromide to elderly patients who might perhaps easily become intoxicated. The same mixture was started again on October 28, and was continued till November 24, when it was again stopped, this time for six days, as a precautionary measure. Again only a slight sedative effect had been produced. During the last week of November, however, she became agitated almost at once, so on November 30 the bromide mixture was given once more. As there was no improvement she was put to bed on December 8, and 10 grains of medinal and 5 units of insulin were ordered twice daily to produce a drowsy, restful condition. After only one dose, however, she was noticed to be perspiring freely and the nurse reported that she did not seem "very well." The case proceeded as follows:

December 9.—Slightly drowsy. Condition satisfactory. Medinal and insulin continued.

December 10.—Very drowsy, so the medinal and insulin were given once only.

December 11.—Still very drowsy, but both doses of medinal and insulin were given. Had to be helped with feeding.

December 12.—Still very drowsy. Fed by nurse. All drugs were stopped. (In addition to the medinal, insulin, and bromide she had been having thyroid for arthritis associated with obesity. She began with 1/2 grain of thyroid in September, the dose being gradually increased till in November she was having 1 grain thrice daily.)

December 13.—The patient was comatose, though her general condition was fairly good. Physical examination did not reveal any abnormal signs in the C.N.S. or other systems, but a most puzzling finding was the presence of glycosuria and a blood sugar of 230 mg. per 100 c.cm., which later in the day rose to 400 mg. The absence of acetone in the urine excluded diabetic coma. No diagnosis was made this day, though an acute cerebral condition—most probably a cerebral

haemorrhage—was considered a possibility. That the coma was due to an idiosyncrasy to barbiturates was ruled out because several months previously she had had the same doses of medinal and insulin daily for two weeks without any ill effects. Bromide intoxication was not seriously considered because of the precautions which had been taken to prevent it and because the development of coma from mere drowsiness had been more rapid than usually occurs in a bromide coma. Treatment consisted in giving plenty of glucose in orange juice and 10 oz. of rectal saline, while later in the day, when the high blood-sugar level was known, treatment with insulin and glucose was started. The blood urea was 50 mg. per 100 c.cm. Full details of urine and blood-sugar examinations, insulin dosage, etc., for December 13–16 are shown in the Table.

Table showing Details of Urine, Blood Sugar, Insulin, etc., during December 13–16, 1939

Date	Urine	Blood Sugar per 100 c.cm.	Insulin Given	Glucose Given
Dec. 13 ..	Sugar ++ (a.m.), s.g. 1022, sugar + + + (p.m.)	2.30 p.m., 230 mg. 5.30 p.m., 400 mg. 11 p.m., 340 mg.	7 p.m., 20 units During night, 80 units	Considerably more than 8 oz. of pure glucose
Dec. 14 ..	S.g. 1042, Sugar + + +, Alb. +, Acetone, nil	10 a.m., 160 mg. 4.15 p.m., 290 mg. 8 p.m., 150 mg. 10.30 p.m., 110 mg.	During day, 60 units During night, 10 units	Not noted, but not a great deal
Dec. 15 ..	Sugar, trace Alb., trace Acetone, nil	10.15 a.m., 150 mg. 5 p.m., 170 mg.	During day, 40 units During night, 20 units	No record
Dec. 16 ..	Sugar, trace Alb., trace Acetone, nil	10.30 a.m., 130 mg.	None	

December 14.—During the night of December 13 the coma deepened very much, and by the next morning she was extremely ill; the pulse ranged from 104 to 120 and the temperature averaged 100°. The blood bromide was estimated early in the morning and was found to be above 400 mg. per 100 c.cm.—an exceedingly high figure—and this knowledge made the unexpected diagnosis of bromide intoxication quite certain. Detoxication was at once started. During the day were given 2 pints of intravenous saline, 4 pints of bland fluids containing a fair amount of glucose by nasal tube, an intravenous injection of mersalyl (as no

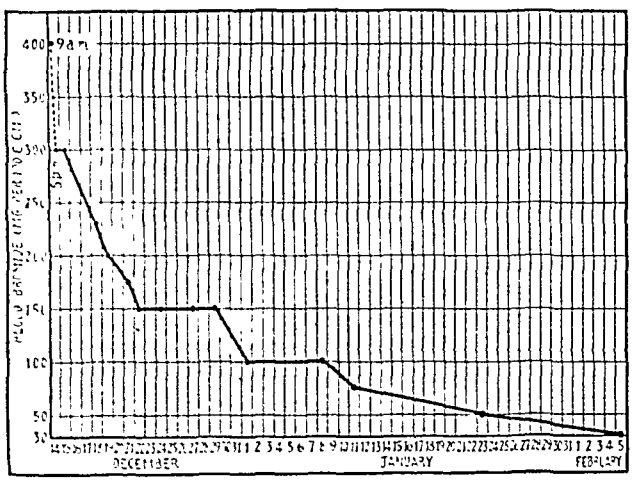

Chart showing the fall in blood-bromide levels from December 14, 1939.

urine had been passed for nine hours), and 30 grains of sodium chloride every four hours. Three injections of nicamide were also given and 70 units of insulin in the twenty-four hours. The second intravenous saline had a dramatic effect, as there were for the first time signs of the coma lessening immediately after it had been given. This energetic treatment lowered the blood bromide to 300 mg. by 5 p.m.

December 15.—She was definitely better and the coma was lighter. The pulse was slower (average 102) and she managed to swallow some fluids unaided. Altogether 6 pints of fluids were given.

December 16.—Further improvement. Temperature normal; pulse 90. Able to swallow quite well. Conscious but confused. From this date progress was rapid, and by January 1, 1940, she was in just the same physical and mental state as before December 8. The accompanying chart shows the fall in blood-bromide levels. A blood-sugar curve and a urea-clearance test done some months later gave normal results.

Summary

The commonest indication for bromide therapy is given, and problems regarding dosage are discussed.

The importance of concurrent psychological help is stressed.

Notes on bromide intoxication and its treatment are given, and a case of almost fatal intoxication is reported.

Another case of severe intoxication is described in which hyperglycaemia and glycosuria were produced.

I wish to record my thanks to Dr. R. D. Lawrence for his helpful criticism and to Dr. D. N. Parfitt, medical superintendent of the Warwick County Mental Hospital, for permission to publish the two cases.

A CONTRIBUTION TO THE STUDY OF HUMAN FERTILITY

BY

JOHN PRYDE, D.Sc.

Lecturer in Chemical Physiology, Physiology Institute, University College of South Wales and Monmouthshire, Cardiff

Divergent opinions are expressed regarding the possible existence within the human intermenstrual cycle of a limited period of fertility. The affirmative views of Knaus and of Ogino are well known. Contrary views—for example, those of Weinstock (1934)—should also be noted. The problem is largely one of collecting reliable statistics, and it is evident that the keeping of day-to-day records by competent observers would materially clarify the position. As a contribution towards this aim I give data abstracted from complete records of sexual activity kept by two pairs of young married partners (all in the early twenties). They fulfilled the necessary experimental conditions of desiring parenthood to follow marriage after an interval of one year or, preferably, two or more years, and, furthermore, were prepared to rely upon a "safe period" procedure, in accord with the views of Knaus, as the primary means of controlling conception.

In both cases the records were kept by the husbands, who noted the date of the start of successive menstrual flows and the date and nature of all acts of intercourse. In both cases positive contraceptive measures were exclusively employed only during the six-day "fertile" period of Knaus—that is, from the tenth to the fifteenth day inclusive following the onset of the preceding menstrual flow. At other times contraceptive measures were largely or entirely dispensed with. As a result in Case A 126 totally uncontracepted acts, distributed throughout the "safe" periods of thirty-three consecutive monthly cycles, preceded the impregnating coitus, and in Case B

450 such uncontracepted acts were similarly distributed throughout sixty-one consecutive monthly cycles. In addition to these, in Case A two further uncontracepted acts just trespassed within the "fertile" period (fourteenth and fifteenth days), and in Case B there was one such further act (fifteenth day). In both cases, when the positive contraceptive measures previously employed during the "fertile" periods were discontinued the desired pregnancies were achieved and followed immediately upon the first uncontracepted acts occurring within the tenth to thirteenth day of the intermenstrual cycles. The figures for uncontracepted acts are alone relevant for our consideration, and Table I records the day-to-day distribution of such acts throughout the thirty-four monthly cycles of Case A and the sixty-two cycles of Case B, the last cycle preceding the establishment of pregnancy being recorded separately from the totals of the preceding non-fertile cycles.

TABLE I.—*Distribution of Acts of Uncontracepted Intercourse*

Totals ..	128		451	

It should be added that both women were reasonably "regular," but there were some few occasions when menstruation was delayed. The duration of all the intermenstrual cycles over which the data extend is given in Table II.

TABLE II.—*Duration of Intermenstrual Cycles*

Duration in Days	25	26	27	28	29	30	31	32	33	34	35	36	37	38	39	40	41	Total
No. of cycles, Case A	0	0	3	7	4	5	8	2	2	0	0	1	0	0	0	0	1	33
No. of cycles, Case B	1	2	4	11	9	15	10	2	2	0	1	1	2	0	0	1	0	61

In Case A the war provided an interesting control in that when pregnancy was desired a short period of leave from service coincided with five of the six "fertile" days and there was naturally considerable sexual activity during this short period. No further cohabitation took place during the remainder of this last cycle in the record. Other points of interest are these. In Case A eighteen uncontracepted acts, and in Case B eight such acts, preceded the tenth day in different cycles (and therefore preceded ovulation) yet did not produce pregnancy. In Case A single acts on the ninth, fourteenth, and fifteenth days and in Case B on the ninth and fifteenth days of different cycles did not produce pregnancy. Further data which I have accumulated lead me to support the view that the type of fertility response shown by the cases described is probably widespread. The present data are published with no controversial aim, but rather with the hope that further day-to-day notes of sexual activity be kept and put on record in cases in which circumstances approximate to those here described. It is necessary to emphasize the importance of day-to-day records. Memory seems to be more than usually fallible in this sphere of human activity.

Summary

Data are given from two cases in which the dates of menstruation and of all acts of intercourse were recorded throughout periods of two and three-quarter and five years respectively. In the former case a total of 126 and in the latter case a total of 450 uncontracepted acts were distributed throughout thirty-three and sixty-one consecutive intermenstrual cycles respectively, at such times that no one of these acts fell within the tenth to the thirteenth day of the cycles. No pregnancy resulted. On the other hand, when pregnancy was desired, it was immediately achieved in both cases following the first uncontracepted acts falling within the tenth to the thirteenth day of the thirty-fourth and sixty-second cycles respectively. These results point to the existence, in the cases described, of a limited period of fertility within the intermenstrual cycle, and afford support for the view that such behaviour may be of more general occurrence.

Finally I should like to add an expression of deep appreciation and thanks for the care and understanding which my young friends gave to the collection of the data.

Clinical Memoranda

Transplacental Tuberculous Infection

The following case may be considered of sufficient interest to merit publication.

CASE HISTORY

A married woman, aged 26, eight months pregnant, was admitted to hospital on April 21, 1939, with a history of headache and vomiting for three days. On admission she was semiconscious and showed clinical evidence of meningitis. Four hours after admission she was delivered of a living female child 5¼ lb. in weight. Lumbar puncture before delivery showed a cloudy cerebrospinal fluid under pressure. Analysis confirmed an increase in lymphocytes and polymorphs, with a decrease in the chloride to 0.62%. A few tubercle bacilli were seen. The mother died on April 24, three days after delivery, without having regained consciousness.

The child, on clinical examination apparently normal for a pregnancy of eight months' duration, gained weight steadily for three months. The feeds, which consisted of secway for the first few days, followed by Cow and Gate half-cream, were well tolerated from the start. At three months enlargement of axillary and inguinal glands was noted, the glands being firm and discrete, with no tendency to break down. The temperature was intermittent in type and the child began to lose weight rapidly. At the same time it developed a cough, but there were no definite clinical findings in the chest. Radiographic examination revealed miliary tuberculosis of

both lungs. Later the liver and spleen became moderately enlarged. The child's condition deteriorated rapidly and it died on August 13, three weeks after the onset of symptoms.

POST-MORTEM FINDINGS

There was extreme emaciation. The heart and pericardium were normal, but both lungs were studded with miliary tubercles, which had coalesced into caseous areas. Large caseating glands were present in the mediastinum. The liver and spleen showed extensive caseous areas, and the kidneys had scattered tubercles in the cortex, with one or two immediately deep to the capsule. The mesenteric glands were large and caseating, and several extensive tuberculous areas were observed in the pancreas. The peritoneum appeared to be quite free from infection.

The child had no contact with the mother after delivery, and owing to domestic circumstances remained in hospital from birth. Members of the families of both parents were interrogated, and so far as could be ascertained there had been no history of tuberculosis in the past on either side. It has since been found that the house in which the woman had been living for the last twelve months of her life had been occupied immediately before by a now known open case of pulmonary tuberculosis.

Unfortunately pathological and bacteriological examination of the placenta was not carried out. Close investigation failed to establish any definite source of infection, and it appears reasonable to suppose that in this case infection was conveyed to the foetus through the placenta.

Acute Malignant Tertian Malaria: Treatment Aided by Reconstituted Serum

Since in several dockside hospitals in the British Isles there have recently been a number of deaths from acute malignant tertian malaria acquired abroad, it is thought that a note on the treatment of one such case might be of interest.

CASE REPORT

An Indian seaman aged 35 was brought into hospital on a stretcher at 2 p.m. on August 18 and was admitted immediately. Owing to the restriction of shipping through the Suez Canal his ship sailed from India via the Cape. She had left Calcutta two months previously, calling at Capetown, and then Freetown, where she lay at anchor for two weeks before proceeding to England. At Freetown no mosquito nets were provided, and soon after leaving the port most of the crew suffered from fever and rigors. The patient had felt strong and well before this trip. Soon after the onset of fever he received on board "some pills and a watery mixture."

On examination he looked very ill; he was rather emaciated, was drowsy, and appeared to be jaundiced. The tongue and mouth were extremely dry and he was very thirsty. The spleen and liver were palpable; the urine was dark, bile-stained, and scanty. He felt very weak and had vomited several times during the preceding few days. The temperature was 102° F., pulse 120, and respirations 28. A blood count showed: red cells, 2,750,000 per c.mm.; white cells, 6,500 per c.mm.; haemoglobin 50%. Many malignant tertian ring forms were detected in every microscopical field. Gametocytes were not seen. The red cells showed secondary anaemia changes, achromia, punctate basophilia, and anisocytosis; some revealed the so-called "brassy" staining of malignant tertian malaria. The case proceeded as follows:

August 18.—At 5 p.m. 9 grains of quinine dihydrochloride was given intramuscularly, and tab. atebrin 1 grain t.i.d., alkaline mist. plus glucose by mouth to excess. At 6 p.m. the patient had a rigor. The temperature was 104°–105°, pulse 128, and respirations 28.

August 19.—At 2.30 p.m. there was no improvement in the patient's condition. He was still very drowsy. The temperature had fallen to subnormal at 10 a.m., but was now 99°. He passed some urine, the reaction being faintly alkaline. Blood smears still showed as many malignant tertian rings as on the previous day. His general condition was causing considerable anxiety. At 2.45 p.m. 7 grains of quinine was injected intravenously, followed by 10 minims of adrenaline subcutaneously. At 3 p.m. 400 c.cm. of reconstituted serum was administered intravenously by the drip method, 40 to 60 drops per minute. The patient's condition at 5.15 p.m. was much improved; his drowsiness had almost gone, he looked quite different, and he smiled and talked intelligently. Fluids were still forced.

August 20.—His condition was very much improved. The temperature rose to 101° F. at 6 a.m., then fell to 99.4° at 10 a.m. and 99° at 2 p.m. and 6 p.m., but increased to 101° again at 10 p.m. No rigors were observed, the patient ate well, and no parasites were seen in blood smears.

August 21.—The patient was getting along nicely. Temperature and urine were normal and he was taking a normal diet. Parasites were not seen in blood smears. He now made what appeared to be an uninterrupted recovery.

COMMENTARY

Until 2.30 p.m. on August 19 the patient had been gravely ill and appeared to be sinking. At this point intravenous quinine followed by reconstituted blood serum was suggested by one of us (A. H. W.), and permission was sought from Dr. P. H. Manson-Bahr to follow this course; he immediately agreed. The improvement in the man's condition after starting this treatment was striking. It is suggested that the action of the reconstituted serum is twofold: it tends to dilute and perhaps to some degree neutralize the circulating malaria toxin, and also to minimize quinine shock, sometimes sustained by toxically debilitated patients of this type.

Our thanks are due to Dr. P. H. Manson-Bahr for permission to try out this treatment and to publish this note.

Pentothal Sodium in Tetanus

Pentothal sodium is of little value in the routine treatment of tetanus owing to its transient effect. In a severe case the actual administration would be difficult, and there may be a considerable local reaction if the drug is accidentally injected outside the vein; while marked trismus might lead to difficulty in maintaining a free airway if the dose given were insufficient to relax the jaw. The drug does, however, seem to have a certain use in such a situation as that here described.

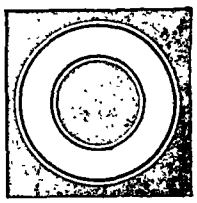
CASE REPORT

A man aged 26 was found to have well-marked tetanic paroxysms eight days after the amputation of two fingers of the right hand which had been crushed by an overturning plough, although he had had 1,000 units of A.T.S. at the time of operation. There was, however, no trismus.

It was decided to give an intravenous injection of pentothal sodium to control the paroxysms during the journey to hospital by ambulance. Ten c.cm. of a 1 in 15 solution (0.66 gramme) was injected into a vein of the left forearm, well clear of the antecubital fossa. A generalized spasm was induced by the prick of the needle, but the arm was easily controlled by an assistant, and induction was otherwise smooth. An airway was inserted, and the journey of about fifteen minutes was completed without incident, the patient remaining relaxed and unconscious and breathing quietly. Shortly before arrival the airway was removed, as masseteric tone was returning and the gagging which often follows closely on this sign might have induced another paroxysm. The patient subsequently recovered from his tetanus after treatment on the usual lines.

Winchester. H. NOEL DAVIS, B.M., B.Ch.

J. Habas (*Thèse de Paris*, 1940, No. 306), who records seven cases in women aged from 23 to 51, states that lactation should not be regarded as the only cause of mastitis, though it presents the most favourable conditions for its development. Mastitis may develop in the course of certain infections such as typhoid fever, in which abscesses with a pure culture of *B. typhosus* are found, and in mumps.



A series of products of

GLAXO LABORATORIES

FOR VITAMIN THERAPY

Vitamin	PRODUCT	DESCRIPTION	POTENCY	FORM
A	PREPALIN	Exceptionally high concentrate of vitamin A for the relief of marked deficiency of the vitamin in all its intensive treatment; especially diseases involving the epithelial structures.	Capsules 24,000 i.u. Liquid, 1 cc. 74,000 i.u. Ampoule 1 cc. 100,000 i.u.	Capsules, boxes of 25 and 100. Tins of 1,000. Liquid, 3 cc. bottle. Ampoules, boxes of 6 × 1 cc. and 12 × 1 cc.
B	BERIN	Pure vitamin B_1 (aneurin) as a sterile aqueous solution for injection, and in tablets for oral use. Indicated in treatment of infantile, pregnancy, gastro-intestinal diseases and whenever deficiency of the vitamin B_1	Tablet, 1 mg. Ampoule, 1 cc., 2 mg.	Tablets, bottles of 25, 100 and 500. Ampoules, boxes of 6 × 1 cc., 12 × 1 cc. and 50 × 1 cc.
	PELONIN Nicotinic Acid *Glaxo*	For the parenteral or oral treatment of pellagra or pellagrinoid symptoms, e.g. Vincent's Disease and stomatitis	Tablet, 50 mg. Ampoule 2 cc. 50 mg.	Tablets, bottles of 25 and 100. Ampoules, boxes of 6 × 2 cc. and 12 × 2 cc.
C	CELIN	Pure vitamin C (ascorbic acid) in stable solution for injection, and in tablets for oral use. For treatment of scurvy and latent scurvy. Indicated also in febrile diseases, haemorrhagic disorders, delayed healing, and as an anti-streptococcic supplement during illness	Tablet, 50 mg. Ampoules, 1 cc., 100 mg.	Tablets, bottles of 25, 100 and 1,000. Ampoules, boxes of 6 × 1 cc., 12 × 1 cc. and 50 × 1 cc.
D	OSTELIN	Pure vitamin D (calciferol) in glycerin. Miscible with water. Specific in the treatment of rickets and indicated in delayed skeletal and dental development. Prescribed with calcium mixtures to ensure their assimilation.	Tablet, 500 i.u. Liquid 1 cc. 5,000 i.u.	Tablets, bottles of 45, 250, 500 and 1,000. Liquid ½ oz. bottle, and bottles of 2 oz., 4 oz. and 8 oz.
	High Potency Ostelin	For oral treatment when exceptionally large dosage of vitamin D is required—as in parathyroid tetany, chronic arthritis, etc.	Tablet, 50,000 i.u.	Tablets, bottles of 25 and 100
E	VITEOLIN	A standardized and concentrated preparation of vitamin E for treatment of habitual and threatened spontaneous abortion. Potency is stated in terms of the recently isolated pure substance (tocopherol).	3 m. capsule contains 6 m.g. tocopherol.	Capsules, boxes of 25, 100, and 500.
K	KAPILON	For the prevention and control of haemorrhage of the newborn and haemorrhage during operation on obstructive jaundice. 'Kapilon' vitamin K analogues completely duplicate the action of vitamin K in restoring prothrombin level and reducing coagulation time.	Ampoule, 1 cc. 5 m.g. Liquid, 10 m.g. per cc. Tablet, 10 m.g.	Ampoules, boxes of 6 × 1 cc. Liquid, ½ oz. bottle. Tablets bottles of 25 and 100.
P	PERMIDIN Hesperidin *Glaxo*	A flavone compound, associated in nature with vitamin C, playing an important part in the regulation of vascular permeability of the capillary wall. Indicated for treatment of certain disorders involving capillary fragility.	Tablet, 0.25 g.m.	Tablets, bottles of 50.
A and D	ADEXOLIN	Concentrated vitamins A and D in balanced ratio. Prescribed as a protective tonic, and as an ante-natal routine.	Capsules, 6,000 i.u. A. 1,000 „ D. Liquid 1 cc., 12,000 i.u. A. 2,000 „ D.	Capsules, bots of 25, 100, 500 and 1,000. Liquid ½ oz. bottle, and bottles of 2 oz., 4 oz. and 8 oz.
	Dekadexolin	Vitamins A and D in exceptional concentration, for injection where massive dosage is indicated.	Ampoule, 1 cc., 60,000 i.u. A. 10,000 i.u. D.	Ampoules, boxes of 6 × 1 cc. and 12 × 1 cc. and 50 × 1 cc.

CLIMACTERIC SYNDROME RELIEVED

"High Doses of Oestrin are usually unnecessary, at any rate for the commoner menopausal symptoms — such as vasomotor disturbances—and consequently oestrin injections are, fortunately, seldom required. It has been my practice to begin with doses of about 500 I.U. daily by mouth. If this does not control the symptoms the dose is raised to 1,000 . . . this is usually completely effective. There are, of course, certain more severe sequelæ of the menopause, which demand much higher doses . . . Pruritis, Kraurosis, Leukoplakia vulvæ, fall into this class and, provided sufficiently high doses are given, the results are little short of miraculous."

Reviews

PSYCHIATRIC CLINICS

Psychiatric Clinics for Children: With Special Reference to State Programs. By Helen Leland Witmer, Ph.D. (Pp. 437. $2.50, or 14s. net.) New York: The Commonwealth Fund; London: Oxford University Press. 1940.

When after the war the social services come to be reconstructed and, it is to be hoped, extended, the "mental side of medicine" will have to be considered equally with the physical side, which has heretofore occupied such a disproportionate amount of attention. Guidance will be required for those concerned both directly as executive officers of the public health and indirectly as the intelligent lay public, whose approval is necessary, in a democratic State, to make any official enterprise a success. Dr. Witmer's book should therefore command a wide circle of readers, for in it she has lucidly surveyed thirty years of experiment in the mental field of medicine in America, where enterprise and resources have both so much exceeded our own.

The author starts with a historical survey of the influences which led to interest in the study of the psychiatry and psychology of childhood. There have been three avenues of approach. The first, the "organic" approach, is based on the theory that structural defects are to be looked upon as the main cause of mental deviation in children. Workers who deal with the subject from this angle will devote attention to the feeble-minded and those with neurological manifestations, and their chief object will be diagnosis and the proper distribution of such children in institutions or in "care," either in their own homes or in foster-homes, with little attention to treatment, since the condition cannot be cured. The second avenue of approach is based on analytic theories, the protagonists of which hoped that by early treatment an appreciable number of people would be kept out of mental hospitals and prisons. Experience has shown, however, that, even in the case of the functional psychoses and delinquency, pathogenic influences are not simple, that it is not easy to pick out those children who are certain or even likely to become psychotic or criminal, and that the attempt to do so is often attended by most unfortunate social consequences. The third means of approach is that of Adolf Meyer (rightly hailed by the author as the father of modern child guidance), whose main object is to afford treatment to those children who seem to require psychiatric help irrespective of ulterior motives for the future.

The second part of the book consists of a survey of the activities and difficulties of a large number of State-aided clinics throughout the Union. Owing to their declared objects, which often have not been fulfilled because of the varied standard of training and personal qualities of the staff, confusion and difficulties have arisen; these are reviewed.

Finally, the three objects of children's clinics as outlined above are discussed in more detail, and the conclusion is reached that the third approach is much the safest. There are undoubtedly very many children, whether supernormal, average, or subnormal in intelligence, who require psychiatric help in their adjustment to life. Such help must be given to the best of professional skill and ability; and if in the process better distribution is achieved of those who require "care," whether in or out of institutions, or if some who would otherwise have become psychotic or criminal do not do so, so much the better, but a start must not be made with claims which are based on ignorance and are therefore unlikely to be justified. In the last chapter is discussed the important subject of State-aided clinics for small and scattered communities. *Altogether this is a most important and useful book.*

VENEREAL DISEASES

Venereal Diseases. By E. T. Burke, D.S.O., M.B., Ch.B.Glasg. (Pp. 550; 133 illustrations and 6 colour plates. 30s. net.) London: H. K. Lewis and Co., Ltd. 1940.

There can be few venereologists who have a wider experience of the subject or who have given more time and thought to it than Colonel Burke, so that his book is sure of a wide circulation, and justly so. It can be said at the outset that as a guide to diagnosis it could hardly be bettered; the clinical pictures are well drawn and the colour plates and photographs are unsurpassed. On the other hand, some of the theories—such as the calculation of the amount of treatment for early syphilis, the therapeutics of bismuth, and the pathology of gonorrhoea—will hardly commend themselves to the average venereologist: a theory, after all, is only a theory till it has been proved, and the propounding of it does not establish it as a fact. In short, this book consists of matter of which 70% is thoroughly sound and 30% highly controversial, not to say heretical. As regards the former, in few books could a reader find so much valuable information put so clearly and succinctly: the clinical acumen of the author perhaps finds expression best in the statement (p. 102), "Over-treatment [of early syphilis] need not be harmful; under-treatment is bound to be disastrous." The latter cannot be discussed in detail within the limits of a short review. Suffice it to say that Colonel Burke has long ploughed a lone furrow in his evaluation of anti-syphilitic therapy and has not yet succeeded in converting any large body of venereologists.

The section on gonorrhoea is altogether admirable, but the reader will do well to ponder over what is said about the bacteriology of that disease and to accept with considerable reserve some of the views put forward.

This volume is well produced and is remarkably free from typographical errors. As constructive criticism it is suggested that rather more might have been said about post-arsphenamine jaundice and that some colour plates showing urethroscopic appearances in chronic urethritis would be a great help to those who have small experience in the use of the urethroscope. The book is hardly one for the unqualified student, as examiners might not approve of some of the views expressed; but there are few venereologists who will not learn something from it, and there is much in it to give them food for thought.

ATLAS OF SKIN DISEASES

An Atlas of the Commoner Skin Diseases. By Henry C. G. Semon, M.A., D.M., F.R.C.P. With 120 plates reproduced by direct colour photography from the living subject, under the direction of Arnold Moritz, B.A., M.B., B.C. Cantab. Second edition. (Pp. 272. 42s. net.) Bristol: John Wright and Sons; London: Simpkin Marshall. 1940.

This atlas, one of the best dermatological atlases yet produced, has deservedly attained a second edition. Seventeen plates, fully up to the standard set by the authors, have been added. Although primarily devoted to the commoner skin diseases—and this is what makes the book so useful—there is an interesting appendix of examples of less common diseases. As evidence of the efforts made by the authors to give the fullest help to the practitioner we may mention that no fewer than twenty-one plates are illustrations of various forms of dermatitis. Not only have new plates been added but

the text, which was always instructive and full of sound suggestions, has been revised and in a few instances corrected. As we noted on the appearance of the original work, colour photography is often a snare and a delusion, and frequently provides pictures that are less recognizable than are monochrome illustrations; but in the present case the authors have given us something that defies criticism. A striking testimony to their excellence is the fact that eight of the plates have been included in the recent new edition of the great French work *La Pratique Dermatologique*. We congratulate the authors on their second edition, but condole with them on the fact that it has had to appear under the shadow of war, which provides an atmosphere by no means conducive to the contemplation of pictorial art. Nevertheless, practitioners will find the atlas very useful and dermatologists will enjoy it.

NUTRITION

The Fundamentals of Nutrition. By Estelle E. Hawley, Ph.D., and Esther E. Maurer-Mast, M.D. Including Table of 100-Calorie Portions, by Estelle E. Hawley, Esther E. Maurer, and Herbert F. Van Epps, and Discussions on the Dietary Management in Specific Conditions. With a foreword by John R. Murlin, Ph.D., Sc.D. (Pp. 477; illustrated. $5.00 post paid, or 27s. 6d.) Baltimore: Charles C. Thomas; London: Baillière, Tindall and Cox. 1940.

The contents of this book fall naturally into four sections. The first deals with the basic facts of the physiology of nutrition, and in the short space of fifty-six pages an excellent review of the problem is given. The second section deals with dietotherapy in disease and in special conditions such as pregnancy, growth, etc. Discussions of the dietary management in specific conditions are contributed by some twenty specialists associated with the School of Medicine and Dentistry in the University of Rochester. The general standard is high, and the modifications of the diets advised are based on sound physiological principles, the influence of faddism or fashion being noticeably absent.

The translation of these scientific principles into practical dietetics for the general practitioner and the housewife is based on a knowledge of tables of foods arranged in 100-calorie portions. These tables occupy thirty-three pages of the book. A great mass of information about the contents of every kind of food is available; this will be most valuable to the professional dietitian. For the general practitioner, however, diet sheets with daily menus and adequate food exchanges appear to the reviewer to be a simpler method of translating scientific principles into practice. Much useful information will also be found in regard to such problems as the planning of diets, the evaluation of nutritional states, the cost, potency, and dosage of commercial vitamin products, the preparation of food for allergic patients, etc.

The book can be recommended with confidence to those who already have some knowledge of the physiology of nutrition and to beginners who wish to make a serious study of the subject.

LAW FOR NURSES

Law for Nurses and Nurse Administrators. By S. R. Speller, LL.B., Barrister-at-Law. (Pp. 206. 10s. 6d.) London: H. K. Lewis. 1940.

The nurse, especially when she becomes senior in her profession, needs to know a surprisingly large amount of law. A matron must have at least a working knowledge of the law of master and servant, sale of goods, defamation, the liability of a hospital for its staff, the law relating to poisonous and dangerous drugs, and a dozen other subjects. The profession badly needed a book on law, and no better author could have appeared than Mr. S. R. Speller. In addition to his legal qualifications he is in close touch with the practical problems of nurses and hospital managers as secretary of the Incorporated Association of Hospital Officers and editor of *The Hospital*. He explains in his preface that his chief difficulty was to know where to set bounds to the work. Certainly within a moderate compass he has covered a very wide range. He gives an outline of English law—always a useful beginning to a book on law for lay persons—and he then sets out the legal basis of the status of a registered nurse and a certified midwife. Other chapters deal with the various contractual relations of a nurse and the difficulties of the master and servant relationship between a nurse and a hospital committee. Termination of service, dismissal without notice, testimonials, and references are discussed in this section. Other practical problems arising out of the loss of a patient's property, the detention of a patient against his will, breach of confidence, mental defectives, insurance, evidence, cheques, wills, and many other legal incidents are concisely treated. It is refreshing to see the very detailed table of contents, which makes any required part of the book easy to find; also the precise documentation of every controversial proposition and the complete references to tables of cases and statutes. Perhaps the author has devoted too much space to setting out the general law. For instance, it is a little difficult to see quite why a nurse—unless she has to answer questions in an examination—needs a list of the contracts which are only valid if set out in a deed, or of those which must be in writing. It might have been better also to confine discussion of the law of sale of goods to the immediate requirements of nurse administrators. Similarly, much of the Public Health Act and Factories Act seems a little outside the ordinary experience of nurses. These, however, are minor details, and the book should be invaluable not only to the nursing profession but also to hospital managers, owners of nursing homes, and persons whose business takes them into contact with nursing. A useful feature is the classified bibliography at the end.

Notes on Books

Dr. R. W. LAWRENCE'S well-known and useful book *The Diabetic Life* (J. and A. Churchill, 9s. 6d.) has now reached a twelfth edition, to which has been added a loose page on "Wartime Precautions for Diabetics." In his preface the author refers to inquiries he has received about food in wartime, and points out that butter and vitaminized margarine are of equal value in the treatment of diabetes. Fresh cream will be missed by many diabetics, but a satisfactory substitute can be made from milk and butter or margarine emulsified in one of the cheap apparatuses now on the market. It is also pointed out that by giving up the sugar ration diabetics receive one extra meat ration and two extra fat rations a week, for which a doctor's certificate is required by the Food Office. Dr. Lawrence well fulfils the object he set himself in the first edition of his book—namely, "to bring the modern treatment of diabetes by diet and insulin within the scope of the general practitioner and the understanding of the patient, whose intelligent co-operation is necessary for the best results."

A fourth edition of *Psychology and Psychotherapy* reminds us again of Dr. WILLIAM BROWN'S extensive culture and wide erudition, but there is still the old complaint of a lack of that cohesion in his system of psychology which we should like to see. He has added chapters on the psychology of later life and on sublimation, both of which are essays only indirectly connected with the rest of the book. Those who read this book for the first time will find much to stimulate thought, and those who already know the author's work will have

pleasure in reminding themselves of the many problems which he has opened up, even though he may not have solved them satisfactorily. The publishers are Edward Arnold and Co., and the price is 12s. 6d. net.

The appearance of a fifth edition of Conybeare's *Textbook of Medicine* (E. and S. Livingstone, 24s. net) shows that it has become firmly established in the affections of those who need a handy compendium of medical knowledge either for passing examinations or for keeping abreast of the times. In the preface the editor points out that his task has been made difficult by the dispersal of his contributors in the Services or in the Emergency Medical Service. The section on cardio-vascular diseases has been thoroughly revised by the editor in conjunction with Dr. Maurice Campbell. Dr. Maurice Mitman has co-operated with Dr. Harries in the revision of the section on infectious diseases. Fresh knowledge of the use of the sulphonamide group of drugs has been incorporated in those parts of the book which deal with the treatment of infections with micro-organisms susceptible to these compounds. Other innovations include an article on congenital cystic disease of the lung, on herniation of the nucleus pulposus, and new radiographs. Revision has in fact brought this well-known textbook up to date.

That a second edition of Mr. EUGENE WOLFF'S *Anatomy of the Eye and Orbit* (H. K. Lewis, 31s. 6d.) should be called for after seven years is evidence of the usefulness of this volume, which is wider in scope than the well-known treatise of Whitnall on the anatomy of the orbit. The book is a clear and profusely illustrated exposition of the more elementary aspects of ocular anatomy. Avoiding the minutiae of the subject, the author includes little that is controversial, though he imparts some individuality by drawing rather freely on his own material. The present edition is richer by some sixty illustrations than the previous edition, and contains a series of drawings of flat sections of the retina. The chapters on the embryology and the comparative anatomy of the eye add to the interest of the work. Much care has obviously been given to the production of this volume, but some of the references are incomplete.

Preparations and Appliances

CUT-OUTS FOR TO-AND-FRO ABSORBERS

Dr. F. BARNETT MALLINSON, honorary anaesthetist, Princess Beatrice, Royal Waterloo, and Woolwich Memorial Hospitals, anaesthetist to E.M.S., writes:

Since I described the absorber cut-out in the *Journal* for May 11, 1940 (p. 774), an improved model has been designed which, while embodying exactly the same principle as the last, has several more convenient features. A photograph of the apparatus is reproduced herewith (Fig. 1) along with diagrams depicting end and side views (Figs. 2 and 3).

The circulation of the gases is as before—passing direct from the face-piece into the canister, thence via the external pipe (P) across into the bag via a separate channel through the cut-out body, and then back again (following the same route reversed) in inspiration. A neater form of control (C) is incorporated, marked "Bag," "S/L," and "Off." The last-named is a new feature which cuts off the bag and allows the patient at the same time to breathe direct to the outside atmosphere; the purpose of this is to conserve the contents of the bag when removing the face-piece for intubation, etc. The port communicating with the air ensures that during the interval between cutting out the bag and unharnessing the face-piece the patient will still have unobstructed respiration.

As in the earlier model, the control will divert any desired proportion of the gases through the canister, but is more accurate and is easier to adjust. There is now no bayonet catch on the barrel of the control, the cut-out being a simple push-fit into the canister. A Waters canister is now generally used, and thus the owner's canister will fit without the need for a bayonet groove. The bag has been mounted in a more convenient position, and has a movable joint, thus ensuring a free and unimpeded situation for the bag, whatever the position of the cut-out or the patient.

If the patient is positioned well down the table so as to leave plenty of room on the head-piece, and his head is placed slightly to one side, it will be found that the face-piece can be applied quite comfortably, and the canister and cut-out will rest easily on the pillow with a little adjustment:

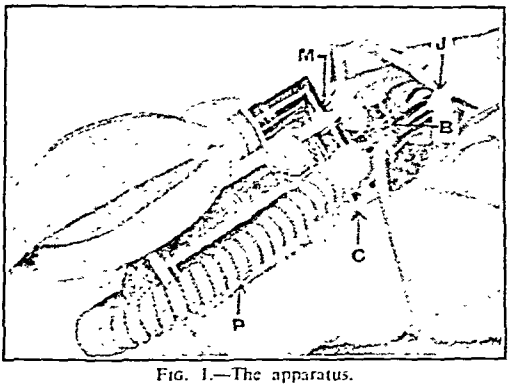

FIG. 1.—The apparatus.

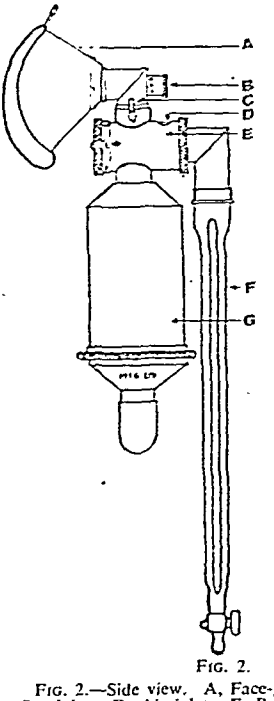

FIG. 2.

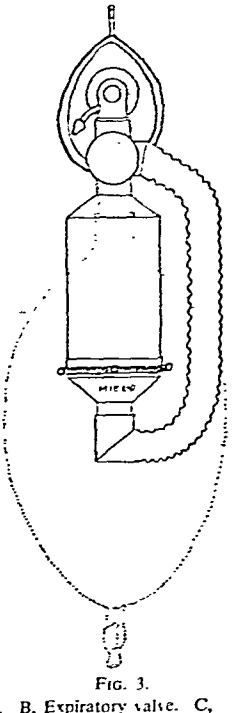

FIG. 3.

FIG. 2.—Side view. A, Face-piece. B, Expiratory valve. C, Gas inlet. D, Air inlet. E, By-pass stopcock with three positions: (1) to-and-fro breathing into bag only; (2) to-and-fro breathing through soda-lime canister and into bag; (3) canister closed both ends, bag closed and contents conserved, patient breathing air during change over. F, Bag. G, Soda-lime container.

FIG. 3.—End view.

face-piece drag does not occur, so no flexible junction is needed. Adjustment can be made: (*a*) horizontally, by rotating the angle-piece (J) in relation to the face-piece; (*b*) vertically, by varying the amount of inclination of the patient's head to the side.

Owing to the elimination of the flexible junction between the face-piece and the apparatus dead space is virtually excluded. Larger ports have reduced internal resistance to negligible proportions. The apparatus was also made for me by the Medical and Industrial Equipment, Ltd., of 12, New Cavendish Street, London, W.1.

IMMUNIZATION AGAINST INFECTION IN THE ARMY

In the recent Harben lectures Lieut.-Colonel H. J. BENSTED gave a valuable review of active immunization in the British Army.

Inoculation against Typhoid

Wright's first injection of typhoid vaccine in 1896 into two I.M.S. officers preceded much anxious work before inoculation was introduced into the Indian Army in 1906. In 1907 C. J. Martin's Committee assessed the evidence, and in 1914, when the war came, T.V., as typhoid vaccine was then called, was available for the immunization of the Expeditionary Forces. In 1915 T.A.B. was introduced. The wise author of the *Medical History of the War* safely prophesied that, as T.A.B. was superior to the vaccine used in the South African War, so would the vaccine of the future surpass the tried friend of 1914–18. From 1928 to 1932 the famous Rawlings strain of typhoid chosen by Leishman troubled the Army authorities responsible for vaccine production through its tendency to roughness in culture. In 1932 Grinnell showed that, though vaccination with certain strains protected mice against lethal doses of typhoid bacilli, the Rawlings strain then in use failed to do so. The Army group—Perry, Findlay, Bensted—and Felix supplied the key: an efficient vaccine must be derived from strains virulent to mice, giving smooth colonies and easily made suspensions and therefore containing O and Vi antigens. Our bacteriological enlightenment during this period is probably reflected in the reduction of enteric incidence in the Army in India from 4 per thousand in 1929 to 1.5 per thousand in 1936, during which time the civil incidence was raised. The Rawlings strain has been "rejuvenated," and, safely sealed on Dorsett egg medium or embedded in "lablemco agar," will continue its beneficent career. It is interesting here to recall that Greenwood and Yule were of opinion that the odds against the great reduction in enteric infections during the first world war being due to chance were 9,999 to 1.

It has been customary to give yearly to forces over-seas a reinforcing dose of T.A.B., the hypothesis being that the duration of immunity is short. Yet the laboratory staff at the Washington Army Medical School in 1939[1] found that the serum of volunteers who had been inoculated from two to ten years previously contained considerable amounts of mouse-protective antibody; after one intracutaneous dose of vaccine they showed as high titre as subjects who for the first time received the regular three doses of vaccine subcutaneously. Hahn, in the great Hanover epidemic in 1926, also found the incidence of infection among men aged 30 to 50 only half that of women of similar age, whereas between 10 and 30 the figure was the same for both sexes. Hahn attributed the escape of so many of the elder men to residual immunity from typhoid vaccination during their army days long previously.

An interesting sidelight on dosage is that in 1923 the half-starved refugees in Thrace responded to the inoculation of the T.A.B. vaccine with very severe reactions. The problem in the future is to maintain the present high immunizing potency of T.A.B. while eliminating the tendency to produce local pain and general malaise. Grasset[2] claims that the injection of efficient immunizing doses of his formolized bacillary extract causes no interruption of work among the coloured mine workers on the Rand. Should this hold good for large numbers of European children and adults the vaccine will be welcome—until in its turn it may be replaced by chemically pure antigen fractions. Colonel Bensted inclined to the view that the universal immunization of the civil population of England is unnecessary, but that since immunization during an epidemic gives virtually the same degree of protection as in non-epidemic periods inoculation may be kept in reserve for sections of the population who may be specially endangered at any time.

Cholera, Plague, Tetanus

Anti-cholera vaccination is in a different category from that with T.A.B. The long array of earnest workers since Ferran first made his injections in 1885 have not yet, in Colonel Bensted's opinion, proved the case for the value of anti-cholera inoculation; nevertheless, he believes that an immunity of short duration occurs. The Inaba and Ogawa strains used by the Army contain the all-important heat-stable O antigen.

It is not easy to assess the value of vaccination against plague, though Taylor's report indicates that the Haffkine vaccine confers a four-fold protection. Schütze's demonstration that the thermolabile envelope antigen produced during growth at 37° C. is essential for protection may result in higher efficiency in future vaccines.

For protection against tetanus in the Army we owe much to the efforts of General Marrian Perry, who in 1936 initiated work by Colonel Boyd at the Royal Army Medical College, in collaboration with the Wellcome Laboratories, to examine Ramon's findings. Toxoid recommended itself, though floccules and alum-toxoid were tried; since the replacement of Witte peptone by peptic digest in the preparation of toxoid, reports of anaphylactic reactions have become even rarer than before. The immunity of the inoculated soldier is sufficiently high to protect him against tetanus, and some 90% of our troops sent to the Continent were actively immunized, but the Army practice is to provide for the unimmunized; therefore all wounded men receive 3,000 international units of tetanus antitoxin, followed, if the patient has not been inoculated, by two weekly doses of 3,000 units. General Perry[3] reported that there have been a few cases of tetanus (actually eight) among unimmunized men, but none so far among the much greater number of immunized. Colonel Bensted called attention to the deadly danger, emphasized by Okell, Colebrook, recently Miles and his colleagues,[4] and others, of ward contamination of wounds with streptococci; he also mentioned—what probably is not so well known—that many extrafaucial infections with diphtheria in the first world war were undoubtedly due to cross-infection during war dressings. "Desert sores" were often found to be due to infection with diphtheria, and Bensted himself has recorded a persistent extrafaucial epidemic on the N.W. Frontier ended only by active immunization.

With regard to vaccination against smallpox, a large proportion of recruits have not been vaccinated in infancy and some of these suffer unusually severe reactions after vaccination. It was also clear from these lectures that the R.A.M.C. maintains a lively interest in vaccination with the stabilized attenuated strain of yellow fever virus cultivated on chick embryo at the Wellcome Bureau; in attempts to protect against influenza with a multivalent strain of influenza virus together with dog distemper virus; and in the Durand protection against typhus with centrifuged lung juice of heavily infected mice.

Colonel Bensted's lectures, though containing nothing strikingly new, constitute a timely record of the sterling work of the R.A.M.C. The British Army is one of the best protected in the world against infection.

MEDICAL PLANNING COMMISSION

As announced in this week's *Supplement*, the British Medical Association has set up a Medical Planning Commission. The matter has been under consideration for some time now in view of the changes that have taken place in the medical services since the beginning of the war. The English Royal Colleges and the Scottish Royal Corporations were invited to co-operate with the B.M.A. in this important work of reconstruction, and have agreed to do so. The Society of Medical Officers of Health, close collaborator of the Association in many matters for many years, has also promised to help. Other bodies represented are the Medical Women's Federation, the Faculty of Radiologists, and the Parliamentary Medical Committee. The Commission starts with a *tabula rasa* upon which to impress its recommendations for the future medical services of this country. It will be bound by no covenant other than its terms of reference, which are: To study wartime developments and their effects on the country's medical services, both present and future. This was amplified by the Chairman of Council at its recent meeting when he said that the time had come for the profession to give serious consideration to the problem of reconstruction and reorganization in the field of medicine in the post-war era.

The Commission has a great opportunity and an equally great responsibility—an opportunity to seize with both hands and a responsibility to call for much searching of heart and mind. It has among its numbers men of all shades of medical experience, and, incidentally, many who are well below the Psalmist's three-score years and ten. Those who are to live and to work in the future must have a prominent voice in deciding what that future shall be. But the visions of the younger men may well be framed in the experience of those whom the years have brought, not stagnation of mind, but the wisdom of maturity. The cynic will be tempted to doubt whether some seventy men, of whatever persuasion, are capable of reaching a common measure of agreement on matters of great moment. He will fear that fundamental principles will be watered down to a solution whose specific gravity will indicate the smallest possible amount of solid matter. He will forecast with glee that compromise will raise its accommodating head when a plain yea would settle a plain issue for men of sound sense. So those who doubt should hold it clearly in mind that the Commission in its full assembly is to be no more—and no less—than a forum for the discussion of the hard facts collected and classified by the committees and subcommittees formed from its number. The Commission is to be the market place in which its members, as sound Athenians, will discuss what is new and reject what is false. It will have one great advantage over the market place in that it will be presided over by a Chairman, whose qualities of tact, discrimination, and judgment will be taxed to the full.

The present war found the medical profession well prepared to play its essential part in the struggle in which the British Empire has now been engaged for some sixteen months. In October, 1937, the British Medical Association started the compilation, in its War Register, of a list of the medical men of this country in terms of their aptitude and desire for service with the Forces or on the home front. The response showed that there was no more loyal section of the population than the medical profession. But patriotism and loyalty have not stifled criticism. Rather has it been tempered in the fire of emotions from which self-interest and sectional interests have receded into the background. War has thrown up into sharp relief the deficiencies of our peacetime system of administering relief to the sick and of promoting and maintaining the health of the people. These deficiencies were, of course, plain enough to many medical men before the war, and the B.M.A. had formulated a series of constructive proposals to deal with them in its report published in 1938 on "A General Medical Service for the Nation," and in other documents. It now proposes to prepare for the return of peace so that Medicine may be ready to meet its responsibilities in a world in which many values will be changed, fresh conceptions of society will be formed, and in which new stresses and strains will appear in the moral, material, and economic fabric of the democracy we hold to be our rightful heritage.

BIOLOGY OF INFECTIOUS DISEASE

Throughout the Middle Ages, and indeed up to some seventy-five years ago when the last epidemic of cholera occurred in this country, infectious diseases were inevitably part of the experience of every citizen. Plague was endemic and at intervals epidemic in all large cities until well on into the seventeenth century; leprosy was without the walls; typhus, small-pox, and later cholera lay in wait for those—and they included the whole population—who flouted the laws of sanitary hygiene. To-day, however, in time of peace, infectious disease is only rarely of primary concern to urbanized Western man. Though he may be worried because his children have measles, annoyed that his office staff should go down with influenza, outraged on the rare occasions when he and his fellows are exposed to the risk of typhoid through contamination of the milk or water supply, he regards all these as matters for his doctor and the public health authorities. Even the doctor, in "resolving the enigma of the fever chart" for his own particular patients, has tended to forget that before all things he is a biologist, an actor in a biological drama which has for its plot the finding of a *modus vivendi* between parasites and their hosts.

When the environment is more or less stable an equilibrium is sooner or later reached, but if the environment is suddenly altered the relations between parasite and host may be violently disturbed. This explains why every major war that has ever taken place has been either accompanied or followed by epidemics of infectious disease. Totalitarian war, with its shifting of entire populations and its enforced return to a life in caves and shelters that man abandoned at the end of the Old Stone Age, gives no promise of differing from

previous conflicts in its association with crowd disease. Infection has once more become of personal interest and importance to us all. It is thus fortunate that in these critical times it is possible to refresh our knowledge of the broad biological aspects of disease by reading a book ably written by Dr. F. M. Burnet,[1] the assistant director of the Walter and Eliza Hall Institute, Melbourne. In his search for the basic facts underlying infection Dr. Burnet takes us back to the very origins of life itself. With our human egotism we are apt to think that man, with discoveries such as those of fire, of the wheel, and of how to work metals or domesticate animals, has alone been responsible for advances in the art of life. Actually the fundamental discoveries were all made by much more primitive organisms: one of these discoveries was that instead of building up the body directly from the air and from such constituents of the earth as are soluble in water it is far simpler to obtain one's food by feeding on other living organisms. To this discovery is due the development of animal life and of all forms of parasitism. Animal nutrition and parasitism are in fact identical in origin, and the work of Metchnikoff in pointing out the similarities between unicellular organisms such as the amoebae and the phagocytic cells of more complex animals is duly emphasized. Incidentally, anyone who wishes to gain some idea of what life was like in Metchnikoff's laboratory should read the entertaining biography of Dr. Etienne Burnet, the distinguished director of the Pasteur Institute of Tunis, written by his talented wife.[2]

The problem of who shall eat and who be eaten is thus a matter of aggression and defence, but whereas the methods of defence are fundamentally the same throughout the animal kingdom the aggressors vary greatly. Of the aggressive parasites, however, only protozoa, bacteria, and viruses are emphasized in Dr. F. M. Burnet's book, worms being dismissed in four lines. This omission is curious, since in tropical and subtropical countries more ill-health is caused by helminthic infections such as ankylostomiasis and bilharziasis than by any other disease, with the exception of malaria. Ankylostomiasis and bilharziasis, in fact, were mainly responsible for the increasing mummification of Egyptian civilization from the end of the Fourth Dynasty onwards. If the one aim of parasites is to obtain as much nourishment as possible at the expense of their hosts, the only real purpose in life would seem to be that of reproduction—an interesting side-light on Whitehead's dictum that the essence of life is that it exists for its own sake, as the intrinsic reaping of value. The death of its host, however, is a disaster for the parasite as much as for the host, and the most successful parasitism is that in which there is a balance between the defence mechanisms of the host and the aggressive actions of the parasite, so that neither host nor parasite is destroyed. An example of such a successful association is seen in the relation of the psittacosis virus to wild parrots, though if, as is suggested, psittacosis arose in Australia, it is difficult to conceive how this or a closely allied virus has become adapted to the fulmar petrel, *Fulmarus glacialis*, for the fulmar petrel is a North Atlantic and North Pacific species of strictly marine habit and can have had little association with the parrots of Australia.

Just as the delicate balance between host and parasite may be upset by changes in the host, so, too, variations may occur in the parasites and new diseases may arise. Apart from encephalitis lethargica, no fewer than ten new virus diseases affecting man have been described in the past twenty-five years, and of these at least nine are capable of attacking the central nervous system. Some of these infections, such as Rift Valley fever and louping-ill, are probably new only in the sense that they have been newly discovered; but with some of the others, such as St. Louis encephalitis, the evidence suggests that they really are of recent development. Although Dr. Burnet does not mention it, unequivocal evidence of a new disease arising in historical times is forthcoming in the case of myxomatosis of rabbits, which must undoubtedly have developed since the Spanish conquest of South America. If, as John Donne remarked long ago, "with new diseases on ourselves we war," it is by no means inconceivable that infectious diseases may have an important part to play in determining the shape of things to come, and a really serious world-wide epidemic would probably do more to set going a sense of genuine co-operation than anything else. Unfortunately, notwithstanding our increased knowledge of infectious diseases, the control of such a pandemic might not be easy, despite the encouraging example set by the hero of James Bridie's *Sleeping Clergyman*.

TREATMENT OF TETANUS

The occurrence of three fatal cases of tetanus in children within a relatively short time led the staff of the department of paediatrics in the College of Medicine, State University of Iowa, to reconsider the treatment employed. This happened about seven years ago, and now Dr. Ralph Spaeth has recorded[1] the clinical histories of approximately the same number of patients with tetanus treated before and since 1933, when modifications were introduced. The principles of the treatment now employed include the systematic use of sedatives, intravenous injection of antitoxin, conservative surgery, and careful general management. With regard to the last, Spaeth urges the creation of special units in charge of persons drilled periodically. For the cases admitted to the University Hospital in Iowa City a printed outline of treatment has been drawn up to facilitate nursing care, especially as regards the maintenance of an adequate fluid and caloric intake and measures to prevent pneumonia. In order to secure an adequate sedative effect avertin is given per rectum with amylene hydrate. Sodium amytal has also been used alone or in conjunction with avertin, and Spaeth recommends an intramuscular injection of a 10% aqueous solution. As to antitoxic therapy, it is stressed that early and intensive treatment must be given to all patients in order to save perhaps only a limited number. In the Iowa new series (since 1933) the intravenous route has been used as the most satisfactory and the dosage has varied between 10,000 and 80,000 units as a single injection. The intrathecal route is strongly condemned. The routine now adopted is 60,000 units for patients admitted during the first five days of the disease and 40,000 units for the mildly to moderately ill patients first treated late. Spaeth sums up as follows the views on surgery of the Iowa school: "Surgical treatment of tetanus ordinarily is not an emergency procedure," and, "The principles of surgery to be followed

[1] *Amer. J. Dis. Child.*, 1940, 60, 130.

in the treatment of tetanus are identical with those recommended in the absence of this disease." In considering the general management of the patient particular care is directed against the risks of pneumonia. When there is prolonged rigidity of the thorax inhalations of carbon dioxide (5 to 10%) in oxygen for ten minutes or so at four-hourly intervals are recommended. Change of position, tepid baths, protection from draughts, and measures to deal with secretions in the mouth or nasopharynx, even including mechanical suction, are all mentioned as important. At the same time an optimal fluid and calorie intake must be obtained, but with a minimal disturbance to the patient. Spaeth emphasizes that it is much more important to keep the patient quiet than to meet theoretical metabolic needs. In discussing the prognosis, comparison is made between the results of the older and the present programmes. Here at once comes the difficulty of the degree of severity of the cases encountered. On a classification of the disease as mild, moderate, and severe, it is found that the incidence of mild tetanus was considerably lower in the new series than in the old. Only seven out of thirty-three patients treated in the past seven years could be called "mild," as compared with seventeen out of thirty-three treated by the older methods. Nevertheless the total mortality rates showed a difference of 9% in favour of the more recently treated patients. The results among those moderate and severe cases admitted during the first four days of the disease showed that the newer methods of treatment secured thirteen recoveries and that there were nine deaths, as compared with three recoveries and ten deaths in the similar groups treated before 1933. Spaeth concludes with a strong plea for the production of active immunity among the population as a whole by the use of toxoid, as with prophylaxis against diphtheria. He also urges the more intelligent use of antitoxin. "Physicians who have encountered numerous cases of tetanus are inclined to administer antitoxin for practically all injuries, whereas those with more limited experience are prone to withhold serum in the presence of minor wounds." Spaeth sums up the indications for the use of antitetanic serum as follows: blank cartridge and powder injuries, penetrating wounds, dirty lacerations, infected burns, self-induced abortions, and injuries of any type in which contamination with soil, dust, or animal dung might have occurred. He suggests 5,000 units as a suitable prophylactic dose, although more is often employed. It should be pointed out that although the majority of the patients discussed in the review were children some adults are also included.

The most debatable item in this policy is the embargo on the intrathecal injection of antitoxin. Sherrington's classical experiments on the effect of antitoxin given by different routes point clearly to the intrathecal as the most effective, and recent observations on the same lines by W. M. Firor[2] lead to the same conclusion. Dogs were given approximately double a lethal dose of tetanus toxin intravenously, and treated with a moderate amount of antitoxin some fifty hours later, when signs of tetanus had become manifest. When this was given by the intracisternal route only three out of thirty-six died, whereas the same dose given intravenously saved only six out of twenty-five. The lumbar intrathecal route was rather less effective than the intracisternal, but still much superior to the intravenous. The treatment of animals with more advanced tetanus was naturally less successful, but even here the results favoured intrathecal administration. Clinical evidence to the same effect and on an impressive scale was put forward by B. B. Yodh[3] in this *Journal* eight years ago. This is therefore at least an open question, if indeed Spaeth's conclusion is not positively wrong.

TREATMENT OF FROST-BITE

Frost-bite, owing to the conditions of trench warfare in the winter months, was a frequent cause of disability during the war of 1914–18, but it has not reached serious proportions in the rather different circumstances of the present war. In the meantime some valuable contributions have been made to the study of peripheral vascular diseases and their treatment by sympathetic denervation. Three recent papers, all of them brief because the work was carried out under conditions of military necessity, make out a good case for fuller and more carefully controlled investigation of the treatment of frost-bite of the hands and feet on the lines of surgery of the sympathetic nervous system. Soupault and Orsoni[1] record a case of bilateral frost-bite of the feet which developed some days after prolonged exposure in the wet and cold. The feet were discoloured, oedematous, cold, and painful, and it was thought that a bilateral Syme's operation would be necessary. After a series of lumbar injections of syncaine there was a marked improvement in the local signs and the subjective symptoms, and ultimately the patient lost only the tips of three toes on one side and the tip of one on the other. Five similar cases recorded by Simon and Filhoulaud,[2] none of them as severe as many seen during the last war, did not come under observation for seven to nine days after the onset of the frost-bite. Two were treated by lumbar injections of novocain and the others by femoral sympathectomy. Good circulatory responses were obtained in all, and it is claimed that necrosis was thereby limited and healing facilitated. Forster and Wiederkehr[3] report the case of a patient who developed frost-bite in one hand after motor-cycling in intense cold and came under observation eight days later. The stellar ganglion was injected by the method of Leriche and Fontaine; vasodilatation, diminution in the swelling and pain, and rapid healing followed. Under conditions of warfare frost-bite is likely to attack young men with healthy arteries—that is, excellent subjects for surgery of the sympathetic nervous system. An approach on these lines is a rational one, since the smaller arterioles are in a state of spasm. At the same time the gangrenous process is one which spreads from the surface towards the deeper tissues. The elimination of vasoconstriction may in the early stages prevent the onset of gangrene, or, when gangrene is established, may limit its spread, diminish pain, assist in the separation of dead tissue, and promote healing.

PSYCHO-ANALYSIS AND PSYCHOSES

Psychiatry, like anthropology generally, owes a great debt to Freud and some of his pupils. They have made some dry bones live, and illumined much that was mysterious. In particular, as by now every schoolboy knows, psycho-analysis has transformed our outlook, if not our treatment of what is conveniently and, *pace* some writers, even scientifically segregated as "psychoneurotic" reaction types. If some people of simple mind have sought to see behind every hysterical paralysis a fixation of the libido at the genital level, this is not the fault of the founder of psycho-analysis. But his success in describing the mental processes in a case of paranoia in "dynamic" terms—that is, as the interplay of competing "mental forces" derived from fundamental instincts and attitudes—has tempted his followers to present a "psycho-analytic psychiatry" *in the sense not only* of a description of psychotic phenomena but in the sense also of causal explanation. For example, Rickman some years ago tabu-

[1] *Mém. Acad. Chir.*, 1940, 66, 358.
[2] Ib'd., 359.
[3] Ibid., 367.

lated the various psychotic syndromes in terms of levels of libidinal development, especially of fixations and regressions therein, and seemed to suggest, in Birnbaum's famous term, a pathogenic as well as a pathoplastic function for these miscarriages. It is true that a schizophrenic dissolution does sometimes allow to appear in full consciousness, as if the repressive barrier had been burst, a set of feelings and ideas which form a textbook illustration of the truth of Freud's views as to the latent content of some people's minds. But is this causal or indicative of at least a constant time-sequence; or is it concomitant only? Is it the complex and the resultant conflict with reality that have disrupted the patient's mind; or has the latter only dissolved backwards along the lines of its evolution? Are we contemplating the volcanic forces behind the earthquake; or only the ruins? This is a question to which there is as yet no agreed answer; but some psycho-analysts appear to have no doubt. This attitude is less excusable when, for example, in a recent paper by Silbermann[1] the facts of observation do not present themselves in ready-made Freudian form but are reformulated by the observer in psycho-analytic language and are then said to "explain" the psychiatric process—in this particular instance a process, under the influence of shock therapy, towards recovery. Briefly, Dr. Silbermann's notion in everyday language is this. The patient receives an alarming form of treatment by which he is so frightened that he appeals to God (a father-figure), having previously neglected the existence of anyone outside himself. Now, however, he remembers to love someone other than his own image. The crucial point at which the patient undergoes the significant psychical experience of complete helplessness is considered to be the few seconds preceding the coma, which is "the deepest level of unconsciousness." But why should this be more significant than other similar kinds of experience—the stages of chloroform narcosis preceding complete unconsciousness, for example? Why, above all, if care is taken to avoid this ultimate experience, as in the method of precardiazol narcotization by N_2O or cyclopropane, or in the electrical method of evoking convulsions, does recovery still occur? This attempt to give a fundamentally psychological, and more particularly a psycho-analytic, account of what happens in shock therapy is another example of the tendency to elevate psychological description into explanation, of which the symbolic interpretation of an epileptic fit, cited in this paper by Dr. Silbermann, is a traditional and, to some minds, particularly unfortunate example, tending to bring the whole of psycho-analytic theory into discredit.

TREATMENT OF TRICHOMONIASIS IN MALES

Although *Trichomonas vaginalis* infestation in males is thought to be comparatively rare, and is certainly so when compared with the incidence of the condition in females, there is evidence that it is commoner than is generally supposed. In many cases, no doubt, the presence of the organism causes no symptoms, but routine examination of cases of chronic gleet would probably reveal trichomonads in a fair proportion. The protozoon, should it succeed in penetrating between the epithelial cells lining the urethra, may produce stricture,[2] and infection of the prostate, bladder, and kidneys may give rise to serious symptoms. Accurate diagnosis and a knowledge of the conditions which favour the growth of this protozoon are essential for successful treatment. Excellent work on this has been done by Liston,[3] who found that the organism thrives best at a *p*H of about 5.5, but cannot long survive at a *p*H of 4—that of the normal vagina—or at one of 7 to 7.5.[4] Early treatment should therefore be the aim, and an attempt should be made to render the urine neutral or slightly alkaline as quickly as possible. For this purpose the bicarbonates and citrates of potassium or sodium are most useful, and they should be persevered with because of the tendency to relapse if treatment is stopped too soon. On the other hand, it would appear, in theory at any rate, that mandelic acid therapy in the form of calcium mandelate might be successful, but it is doubtful whether it would be possible to keep the *p*H at a low enough level for a sufficient length of time to destroy all the organisms. Acriflavine, given orally in half-grain "enteric-coated" tablets, and sulphanilamide have been tried with doubtful success. Various local remedies, including devegan or stovarsol, silver picrate, and negatol, have been used successfully in cases of vaginitis. Negatol may be employed in the male as a urethral irrigation or instillation in a strength of 1% to 2%. Experience has shown that routine irrigation with the usual antiseptics, such as potassium permanganate, is not only useless but may be positively harmful, though some workers employ mercury oxycyanide. Where the infestation is only superficial maintenance of a urine *p*H of 7 to 7.5 will probably be successful, but when the submucous tissues are involved local treatment is indicated. In all cases failing to clear up with alkalis an endeavour should be made to locate lesions in the urethral canal. Infected follicles and submucous infiltrates, which if left untreated might lead to stricture formation, should be dealt with by either massage over a straight sound or the use of Kollmann's dilator. In some instances it may be necessary to employ the cautery, which should always be followed by dilatation, as strictures are more easily prevented than cured. If symptoms of prostatitis occur appropriate treatment consists in regular massage and diathermy. Cystitis has been treated successfully by daily irrigation with 1 in 1,000 nitrate of silver, and pyelitis by lavage of the pelves of the kidneys with 2% mercurochrome; in both these conditions it is worth while keeping the urine alkaline. It cannot be too strongly stressed that success in treatment depends on starting it before the organisms have got out of reach beneath the mucous membrane, and on maintaining it for some time after all symptoms have subsided. Nor should it be forgotten that in the case of a married man the wife is almost certainly infected also, and it is useless to treat the one and not the other.

INTRANASAL IMMUNIZATION

The Chinese for many centuries, it is said, have attempted to produce immunity against small-pox by the intranasal instillation of variolous material. That this method of immunization has a sound scientific basis has been proved by a number of observations during the past few years, while the method has been shown to be applicable to a wide variety of antigens. Attention to the possibilities of producing immunity against diphtheria by intranasal instillation was first directed by Ramon and Zoeller[5] and later by Jensen,[6] who immunized a number of children with diphtheria toxoid by this route. Fraser, Davey, and Halpern[3] in Canada have now further studied the antitoxin response in children and adults treated intranasally with concentrated and purified diphtheria toxoid, the preparations used having Lf values of 900 and 850 per c.cm. The technique consisted in soaking a small pledget of

[4] *C. r. Soc. Biol.*, Paris, 1927, 97, 701.
[5] *Proc. roy. Soc. Med.*, 1937, 30, 1117.
[6] *Canad. Publ. Hlth. J.*, 1940, 31, 376.

absorbent cotton-wool in 0.5 c.cm. of toxoid and inserting it through the anterior nares till it rested between the septum and the anterior end of the inferior turbinate. The pledget remained in the nose from fifteen minutes to six hours. The antitoxin titre was tested before and after immunization, and though the individual response varied greatly, 83% of the entire group showed a good response. The Canadian workers, however, regard intranasal instillation as more suitable for reinforcing antitoxic immunity than for primary inoculation. In Japan, Kodama, Sato, and Hata[1] believe that by intranasal instillation of toxoids it is possible to bring about an effective immunity against such conditions as diphtheria, tetanus, and streptococcal and staphylococcal infections. The effects of nasal immunization are said to be more definite if, instead of saline solutions, glycerin carbolic saline solutions of the toxoids are used, as these mixtures permit much longer contact with the nasal mucosa. No undue reaction was noted in children when they were treated with a mixture of different toxoids—in fact, the effect on the production of antitoxins was more pronounced than when only a single toxoid was employed. Intranasal reimmunization invariably stimulated a rapid and high production of antitoxin. The possibility of immunizing against whooping-cough by the intranasal route has also been considered by Dow.[2] Mice, it was found, could be actively immunized intranasally with the antigens of *Haemophilus pertussis*, the results being sufficiently clear-cut to admit of a comparison of the antigenic powers of various antigenic fractions. Actually, whole vaccines of *H. pertussis* gave more effective immunization than so-called soluble antigens. After the successful immunization of mice by intranasal instillation, active immunization of human beings was attempted, the nasal mucosa being first treated by an instillation of gluco-fedrine. No unpleasant reactions were encountered, and the serum of one person so immunized was found to possess sufficient antibody to be used prophylactically with success in two children who had been exposed to infection with whooping-cough.

BAN ON HIGH-FREQUENCY APPARATUS

It is necessary to draw attention once more to the restrictions which have been placed by an Order of the Home Office on the use of high-frequency apparatus. Although the Order, which was published in full in the *Journal* of September 7 (p. 333), came into effect on September 2, many practitioners still possess high-frequency apparatus without being aware that they should have reported the fact. The Order provides that no person may have such apparatus in his possession except under permit of the Postmaster-General. The apparatus includes diathermy and electro-medical equipment using valves or spark coils. Unauthorized possession constitutes an offence under the Defence Regulations, and any possessor who has not either applied for a permit from the Engineer in Chief, Radio Branch, General Post Office, Harrogate, or reported his possession to the local police, should do so at once. At the time the Order was issued the British Medical Association sent an expert representative to discuss the matter with the authorities concerned, and it was found, and later agreed by the Physical Medicine Group Committee of the Association, that the measures taken were fully justified and "were in no way out of proportion to the exigencies of the moment." The immediate object was to reduce the number of sources of electrical disturbance and to effect some measure of centralization which would facilitate exercise of control and enforcement of precautions directed towards the abolition of interference by screening and the use of filters. This is a Home Office Order made under the Defence Regulations, and owners of apparatus to which it refers must make known that fact in their own interests and those of national security.

THE NEW YEAR HONOURS LIST

A list of the New Year Honours conferred on members of the medical profession will be found at page 25. A baronetcy has been conferred on Mr. Hugh Lett, President of the Royal College of Surgeons. The Hon. Godfrey Martin Huggins, F.R.C.S., Prime Minister of Southern Rhodesia since 1933, receives the K.C.M.G. The K.C.I.E. has been bestowed on Major-General E. W. C. Bradfield, medical adviser to the Secretary of State for India and lately Director-General, Indian Medical Service. Dr. J. H. Hebb, Director-General of the Emergency Medical Services, Colonel C. T. Champion de Crespigny, a leading Australian physician, and Brevet Colonel Ram Nath Chopra, Professor of Pharmacology and Director of the School of Tropical Medicine, Calcutta, receive the honour of Knighthood. Dr. A. G. H. Smart, medical adviser to the Secretary of State for the Colonies, and Dr. R. T. Leiper, F.R.S., Professor of Helminthology in the University of London and Director of the Department of Parasitology at the London School of Hygiene and Tropical Medicine, both receive the C.M.G. Members of the British Medical Association will note with pleasure that Dr. R. W. Craig, Scottish Secretary, has been awarded the O.B.E., and Mr. A. T. Twelftree, Chief Clerk to the Association and to the Central Medical War Committee, the M.B.E.

"MEDICAL DIRECTORY," 1941

The ninety-seventh edition of the *Medical Directory* has been published by Messrs. J. and A. Churchill, Ltd. The typographical improvements introduced last year are repeated, and the arrangement of the *Directory* and its price (42s.) remain the same. There has been a net increase of 1,457 entries, while the number of pages of text has increased by thirty-two. The numerical summary of the medical profession shows that there are now 64,304 names, compared with 62,847 in 1940. Increases will be found in most of the sections of the *Directory*: 895 under Provinces, 75 under Abroad, 277 under Scotland, 265 under Ireland, and 96 under Wales. Two decreases are recorded: 85 under London and 66 under Services.

Dr. R. A. O'Brien, C.B.E., who joined the staff of the Wellcome Physiological Research Laboratories at Beckenham in 1910 and became director in 1914, retired at the end of 1940. Dr. J. W. Trevan, who became head of the pharmacological section in 1920, has been appointed to succeed him.

Already about 100 fully trained State-registered nurses have been allocated to various London boroughs for shelter work. More nurses, either trained or auxiliary, have been supplied locally, and the total available is now over 300. Fully trained nurses receive an inclusive salary of three guineas a week. Hours of duty are approximately ninety-six a fortnight, involving alternate nights on duty while the hours of blackout are at their longest. Four part-time shelter matrons are being appointed by the Ministry of Health to visit and supervise the nursing personnel in the shelters in consultation with the medical officers.

HEALTH IN THE SHELTERS

FURTHER RECOMMENDATIONS BY LORD HORDER'S COMMITTEE

Further proposals of Lord Horder's Committee on health in air raid shelters have been presented to Parliament by the Minister of Health and the Minister of Home Security and are now published as a White Paper.* The recommendations and the action of the Government taken thereon are printed below.

Tuberculosis

(i) That arrangements be made to hospitalize at once cases of "open" tuberculosis known to frequent shelters. If necessary, compulsory powers should be taken to effect this.

(ii) As far as possible each tuberculous family should have a family shelter and should obtain priority in the issue of an Anderson shelter or of other assisted shelter accommodation.

Local Authorities and Medical Officers of Health have been urged to see that action is taken along these lines. The necessary compulsory powers have been obtained.

Louse Infestation

(i) The Committee endorsed the action taken by the Ministry of Health for arranging (*a*) short courses of instruction at the London School of Hygiene for shelter wardens; and (*b*) the preparation and issue of a short pamphlet suitable for shelter wardens giving briefly the essential facts in the life history of the louse, the flea, and the bed-bug, and summarizing simple measures for dealing with these pests.

(ii) Selected insecticides should be made available and the methods of their application should be submitted to trial. The method or methods chosen should be set out in a leaflet for the guidance of wardens acting under medical supervision.

(iii) If compulsory powers to delouse do not at present exist they should be taken immediately.

(iv) The advisability of obtaining more accurate information in regard to the incidence of louse infestation in shelters is recognized. To this end the inquiries which have been already set on foot should be extended to other areas.

Medical officers of health are now reviewing the facilities available in their areas for cleansing. Where these are inadequate the necessary cost of making additional provision to meet the needs of persons attending public shelters will be reimbursed to the local authorities by the Ministry of Health. The Ministry is also taking steps to establish a supplementary service of mobile disinfesting units so far as supplies of necessary materials and labour permit. Quantities of the insecticides recommended have been ordered, and instructions for use, based on the results of trials, will be issued. The compulsory powers referred to have been obtained. The investigation of lice incidence will be extended as soon as methods and technique are further developed.

Bug infestation in Shelters

(i) In the construction of shelters, bunks, and other fittings, measures should, as far as possible, be taken to avoid cracks, crevices, and other harbourages for insects. To this end the Committee suggests that the practicability of treating all internal walls with impermeable paint to render them impervious to bugs should be investigated.

(ii) When a shelter is found to be infested the Committee suggests the adoption of the following method, which should result in a large measure of success, namely:

An organized system of cleaning and scrubbing and the liberal use of soap and water containing cresol. The use of a painter's blow lamp carefully applied to all cracks, etc., is an excellent simple method, which is generally applicable for small infestations.

Instructions on this matter are on the point of being issued to the authorities concerned.

Chemicals in Latrines

In view of the need for economy the Committee would point out that it is usually unnecessary to use disinfectants in latrine containers when these are being flushed or emptied frequently and regularly.

Instructions are being issued on this.

Masks

In response to a request from the Minister of Health the question of the use of masks by shelter users was submitted to an *ad hoc* Committee. Two representatives of the Medical Research Council were co-opted and have carried out helpful researches. The following tentative recommendations have been accepted by the main Committee. Meanwhile the researches referred to are being continued.

(i) The principle of the mask for reducing the risk of droplet infection is sound and should be capable of practical application.

(ii) It seems desirable to choose as a standard a type of mask that will best serve the dual purpose of reducing the spread of micro-organisms from an infected person, and, at the same time, of protecting as far as possible the uninfected person.

Bearing in mind the importance of availability of material, ease of adjustment to the face, and rapidity and thoroughness of disinfection, in addition to the main consideration of actual protection, a cellulose acetate (cellophane) screen, 5½ in. square supported by an elastic cord, is considered to be the best for standard purposes. A suitable number of such masks should be ordered so as to meet the arrival of any contingency. To obviate an unforeseen difficulty in the supply of cellophane, masks of the gauze type, consisting of at least four layers of muslin of at least forty-four threads to the inch, should also be ordered.

(iii) The yashmak type of mask, which some persons prefer to wear, and which is being commercialized, is regarded favourably by the Committee.

(iv) A memorandum for the information of medical officers of health concerning the use of masks should be issued. A leaflet should also be prepared for issue to shelter users when the necessity arises.

Orders for large numbers of the types of masks recommended in subsection (ii) above have been placed, and arrangements are being made whereby further supplies may be quickly obtained should the necessity arise. A memorandum and leaflet on the lines proposed in subsection (iv) have been prepared.

Lozenges, Gargles, and Throat Sprays

The Committee has considered the use of certain reputed prophylactic measures such as medicated lozenges, gargles, and throat sprays. From the evidence placed before it the Committee concludes that there are not sufficient grounds on which to recommend any of these methods as part of the general hygiene campaign against infection in shelters. At the same time the Committee does not wish to discourage the use of these measures by individual shelter users. It does not, however, advise that these kinds of medicaments be included in the list of drugs supplied by Government.

Smoking

(i) In the interests of public health, smoking should be prohibited in public shelters except where a separate compartment can be set aside for smokers.

(ii) This prohibition does not, of course, apply to any form of domestic shelter or domestic communal shelter.

(iii) Facilities for smoking can usually be provided in the brick surface public shelters by setting aside a compartment for the purpose.

(iv) It is suggested that, in order to avoid confusion in the public mind, the different categories of shelter should be carefully explained to the Press if, and when, this recommendation is handed to them.

* H.M. Stationery Office. Cmd. 6245. (Price 1d. net.)

The Public Shelter Rules made under Regulation 23AB of the Defence (General) Regulations, 1939, contain provisions enabling smoking to be prohibited or controlled according to circumstances.

Other Points under Consideration

The Committee is sponsoring certain controlled experiments with some of the newer forms of chemotherapeutic drugs, used as nose and throat sprays under medical supervision, and these are still in progress.

NEW YEAR HONOURS

The names of the following members of the medical profession were included in a New Year Honours List published in a Supplement to the *London Gazette* on December 31, 1940.

Baronetcy

HUGH LETT, C.B.E., M.B., Ch.B. President of the Royal College of Surgeons of England.

K.C.M.G.

The Hon. GODFREY MARTIN HUGGINS, F.R.C.S. Prime Minister of Southern Rhodesia since 1933. On the occasion of the Jubilee celebrations of the Colony.

K.C.I.E.

ERNEST WILLIAM CHARLES BRADFIELD, C.I.E., O.B.E., M.B., M.S., F.R.C.S.Ed. Major-General, Indian Medical Service. Medical Adviser to the Secretary of State for India and lately Director-General, Indian Medical Service.

Knighthood

RAM NATH CHOPRA, C.I.E., M.D. Brevet Colonel I.M.S. (ret.). Professor of Pharmacology and Director, School of Tropical Medicine, Calcutta.

CONSTANTINE TRENT CHAMPION DE CRESPIGNY, D.S.O., V.D., M.D., F.R.C.P. For public services in the Commonwealth of Australia.

JOHN HARRY HEBB, C.B., C.B.E., M.B., B.Ch. Director-General, Emergency Medical Services, Ministry of Health.

C.B. (Military)

ROBERT WALTER DICKSON LESLIE, O.B.E., L.R.C.P. & S.I. Major-General, late Royal Army Medical Corps. Honorary Physician to the King.

JOHN WALTER LENNOX SCOTT, D.S.O., M.R.C.S., L.R.C.P. Major-General, late Royal Army Medical Corps. Honorary Physician to the King.

CECIL PEMEREY GREY WAKELEY, D.Sc., F.R.C.S., F.A.C.S., F.R.A.C.S. Temporary Surgeon Rear-Admiral, Royal Navy.

C.S.I.

HUGH CLIVE BUCKLEY, M.D., F.R.C.S. Major-General, Indian Medical Service. Honorary Physician to the King. Lately Surgeon-General with the Government of Bombay.

C.M.G.

JOSEPH WELSH PARK HARKNESS, O.B.E., M.B., B.Ch., D.P.H., Colonial Medical Service. Director of Medical Services, Gold Coast.

ROBERT THOMSON LEIPER, D.Sc., M.D., F.R.S., F.R.C.P., Professor of Helminthology in the University of London and a Director of the Department of Parasitology, London School of Hygiene and Tropical Medicine.

ERIC DENHOLM PRIDIE, D.S.O., O.B.E., M.B., B.S. Director of the Sudan Medical Service.

ARCHIBALD GUELPH HOLDSWORTH SMART, M.B.E., M.D., D.P.H. Medical Adviser to the Secretary of State for the Colonies.

BERNARD TRAUGOTT ZWAR, M.D., M.S., F.R.A.C.S. President, Royal Melbourne Hospital, State of Victoria. For public services.

C.I.E.

DAVID CLYDE, M.D., D.P.H. Lieutenant-Colonel, Indian Medical Service. Civil Surgeon, Lucknow, United Provinces.

WALTER HUGH CRICHTON, M.B., Ch.B., D.P.H. Lieutenant-Colonel, Indian Medical Service. Chief Health Officer, Delhi.

HENRY HAWES ELLIOT, M.B.E., M.C., M.B., B.S., F.R.C.S. Lieutenant-Colonel, Indian Medical Service. Surgeon to His Excellency the Viceroy.

HENRY EDWARD SHORTT, M.D. Lieutenant-Colonel, Indian Medical Service. Director, King Institute, Guindy, Madras.

C.V.O.

EDMUND CLAUD MALDEN, M.B., B.Ch.

C.B.E. (Military)

ROBERT FRANCIS PRESTON CORY, M.R.C.S., L.R.C.P. Surgeon Captain, Royal Navy.

FRANCIS ROSSALL SANDFORD, M.C., M.B., B.Ch. Colonel, late Royal Army Medical Corps.

C.B.E. (Civil)

Lady RUTH BALFOUR, M.R.C.S., L.R.C.P., Chairman, Women's Voluntary Services for Civil Defence in Scotland.

THOMAS HERBERT GODDARD, M.B. For devoted services to public and philanthropic movements in the State of Tasmania.

ARTHUR HUTTON MCSHINE, O.B.E., M.D., C.M. For public services in Trinidad.

Mrs. RUTH YOUNG, M.B.E., M.B., Ch.B., Women's Medical Service. Lately Principal, Lady Hardinge Medical College, Delhi.

M.V.O. (Fourth Class)

GEORGE PROCTOR MIDDLETON, M.B., Ch.B.

O.B.E. (Military)

REGINALD ANSON MANSELL, M.B.E., M.B. Major, Royal Army Medical Corps.

ALFRED WILLIAM NORTH, L.M.S.S.A. Surgeon Commander, Royal Navy.

ARNOLD ASHWORTH POMFRET, M.B., Ch.B., D.O., D.O.M.S. Surgeon-Commander, Royal Navy.

O.B.E. (Civil)

Mrs. KATIE ARDILL-BRICE, M.B., Ch.M. For philanthropic and welfare work in the State of New South Wales.

JAMES HAMILTON CAMPBELL, D.S.O., M.B., B.Ch. Colonel, Royal Army Medical Corps (retired). Air Raid Precautions Controller, Kent.

ROBERT WILLIAM CRAIG, M.D. Scottish Secretary, British Medical Association. For services in connexion with civil defence.

CLYDE CORNWALL FENTON, M.B. Flying Officer, Royal Australian Air Force. Lately Medical Officer, Northern Territory Medical Service, Commonwealth of Australia.

SYDNEY NUTTALL HAYES, F.R.C.S., F.R.C.O.G. Lieutenant-Colonel, Indian Medical Service. Professor of Midwifery, King Edward Medical College, Lahore, and Medical Superintendent, Lady Willingdon Hospital, Lahore, Punjab.

GEORGE KINNEARD, M.D. Colonial Medical Service. Senior Medical Officer, Falkland Islands.

GOPAL DAS MALHOUTRA, M.B., B.S. Lieutenant-Colonel, Indian Medical Service. Civil Surgeon, Moradabad, United Provinces.

SULTAN BAKSH MALIK, M.R.C.S., L.R.C.P. For public services in the Tanganyika Territory.

SHAMRAO RAMRAO MOOLGAVKAR, F.R.C.S. Professor of Surgery, Grant Medical College, and Honorary Surgeon, J.J. Hospital, Bombay.

ARTHUR AUBREY PALMER, M.B., C.M., F.R.C.S. For public services in the State of New South Wales.

JOSEPH FRANCIS ENGLEDUE PRIDEAUX, M.R.C.S., L.R.C.P. Director of Medical Services, Ministry of Pensions.

JOHN WIGHTMAN STIRLING, M.B., Ch.B., J.P. Principal Medical Officer, Bechuanaland Protectorate.

MOORE TAYLOR, M.D., D.P.H. Major, Indian Medical Service. Superintendent, European Mental Hospital, Kanke, Ranchi, Bihar.

M.B.E. (Civil)

FRED BARRETTO, L.M. & S., D.P.H. Assistant Director of Public Health, in charge of the Public Health Laboratory, Poona, Bombay.

GERALD HUGH BLAKER. Captain, Indian Medical Department (retired).

Miss MARIE CÔTÉ. Retired Medical Practitioner, Thandaung, Toungoo District, Burma.

Mrs. DOSSIBAI JEHANGIR RATANSHAW DADABHOY, M.D., M.R.C.P. Honorary Consulting Surgeon, Cama and Albless Hospitals, Bombay.

Rai Bahadur NAGENDRA NATH DUTT. Honorary Captain. Medical Practitioner, Calcutta.

CHARLES NORMAN GRIFFIN, M.D. Colonial Medical Service. District Medical Officer, St. Kitts, Leeward Islands.

WILLIAM ST. ALBAN HENDRICKS, L.M.S. Assistant Surgeon. Civil Surgeon, Gangtok, Sikkim.

Miss URSULA MARIE LOBO. Women's Medical Service, Junior Branch, Shegaon, Buldana District, Central Provinces and Berar.

ANTONIO JOSE NORONHA, M.D., F.C.P.S. Lecturer in Bacteriology and Pathology, B.J. Medical School, Poona, Bombay.

ANTONY JOHN SELVEY. Assistant Surgeon. Acting Vice-Consul and Medical Officer, British Consulate-General, Kashgar.

SAYAD HABIBULLAH SHAH. Major, Punjab Civil Medical Service, *Army in India Reserve of Officers*. Superintendent, Old Central Jail, Multan, Punjab.

WILFRID REGINALD TAYLOR, M.R.C.S., L.R.C.P., D.P.H. Assistant Medical Officer, Grimsby. For services in connexion with civil defence.

RAGHUNATH SABAJIRAO TIRODKAR, M.D. Professor of Medicine, Grant Medical College, and Honorary Physician, J.J. Hospital, Bombay.

D.S.C.

THOMAS BENEDICT FITZGERALD, M.B., Ch.B. Surgeon Lieutenant, Royal Naval Volunteer Reserve.

JOHN THOMAS, M.R.C.S., L.R.C.P. Surgeon Lieutenant, Royal Navy.

M.C.

KEVIN CORMACK DONOVAN, M.B., B.S. Flight Lieutenant, Royal Air Force Volunteer Reserve.

Air Force Cross

HUGH WOLFE CORNER, M.D., Ch.B., M.R.C.P. Wing Commander, Royal Air Force.

Bar to Kaisar-i-Hind Gold Medal

Mrs. OLIVE MONAHAN, M.D. Chief Medical Officer (retired), Kalyani Hospital, Madras.

Kaisar-i-Hind Gold Medal

ROBERT GREENHILL COCHRANE, M.D., M.R.C.P. Medical Superintendent, Lady Willingdon Leper Settlement, Chingleput, Madras.

Miss REBA CUTHBERT HUNSBERGER, M.D. Lady Doctor-in-Charge, Memorial Hospital for Women and Children, Sialkot City, Punjab.

WILLIAM PATRICK SMYTHE MITCHELL, M.B.E. Lieutenant, Indian Medical Department. Chief Medical Officer, Bastar State.

Mrs. DAISY ELIZABETH MUNRO, M.B.E. Lady Superintendent, Civil Hospital, Karachi, Sind.

JOSEPH LOCKHART DOWNES YULE, M.B., Ch.B. Lieutenant-Colonel, Indian Medical Service. Lately Officer Commanding, Indian Military Hospital, Delhi Cantonments.

Mentions in Dispatches

JOHN CAMPBELL HILL AITAN, M.B., Ch.B. Acting Wing Commander, Auxiliary Air Force.

FRANK CUNNINGHAME COWTAN, M.R.C.S., L.R.C.P. Air Commodore, Royal Air Force.

FREDERICK MITCHELL DUTHIE, M.B., Ch.B. Surgeon Lieutenant-Commander, Royal Navy.

JAMES HILL, M.B., Ch.B., D.P.H. Wing Commander, Royal Air Force.

REGINALD HERBERT KNOWLES, M.D., D.P.H. Group Captain, Royal Air Force.

THOMAS CLOVER LARKWORTHY, M.B., B.S. Acting Surgeon Commander, Royal Naval Volunteer Reserve.

DAVID ANDERSON SMITH, M.B., Ch.B. Flight Lieutenant Auxiliary Air Force.

GEORGE JON WALLEY, B.M., B.Ch. Temporary Surgeon Lieutenant, Royal Naval Volunteer Reserve.

Reports of Societies

HYGIENE IN AIR-RAID SHELTERS

A discussion on "Hygiene in Air-raid Shelters" was held at a meeting of the Section of Epidemiology and State Medicine of the Royal Society of Medicine on December 20, Dr. J. ALISON GLOVER presiding.

Dr. P. G. STOCK (Ministry of Health) gave a brief history of recent events. With the onset of the air offensive there was a rush to the tubes. The herd instinct asserted itself in the desire for human companionship, which led to the desertion of the domestic for the communal shelter, with overcrowding of the latter. In many cases the people sought refuge in places which had never been approved as shelters. Until this state of affairs developed, questions relating to shelters had come under the Ministry of Home Security, and medical officers of health had not been expected to interest themselves in the matter. On September 25 the Chief Medical Officer of the Ministry of Health addressed a letter to the medical officers of the metropolitan boroughs asking them to carry out instructions regarding public air-raid shelters in their areas, but by mid-October, for one reason or another, little improvement was apparent in the sanitary conditions. Shortage of materials and labour contributed to the difficulty. Additional medical officers were detailed to visit shelters and co-operate with the public authorities. The fundamental problem was overcrowding, with its attendant evils of defective ventilation and lack of sanitation. Another serious defect in many shelters was dampness due to faulty roofing, flooding of entrances with storm water, or condensation of moisture on the walls. Apart from the deep tube stations lighting was inadequate and badly placed. In many shelters there were no means of artificial heating in cold weather. In many also there was an absence of piped water supply.

The Ministry of Health was not, as some of its ill-informed critics supposed, content to sit back with folded hands after having issued its circulars. Dr. Stock mentioned with high appreciation the personal interest of the Minister, Mr. Malcolm MacDonald. Everything possible was being done to secure the voluntary evacuation of children, of mothers with young children, and of expectant mothers. A ticket system for habitual shelterers had been introduced. A resurvey had been made to discover further shelter accommodation. At the same time it had to be admitted that such a degree of overcrowding still existed as no medical officer of health could regard with equanimity. As to ventilation, early in October a committee was appointed to consider this question, along with that of heating, and efforts were made to improve conditions by installation of fans, opening up of shafts hitherto closed, and other measures. After considerable hesitation it had been decided to put in coal-burning stoves for use in public surface shelters holding fifty persons or more in one compartment. Experiments were being made with electric heating, but the supply question rendered this impracticable in the majority of shelters.

In shelters where the night population was 500 or over the local authorities had been asked to establish medical aid posts, the cost of equipment being the responsibility of the Exchequer. He showed the meeting a plan of a post for a tube station. It consisted of two main apartments: one containing a number of bunks, a cupboard for dressings and medicines, and a dressing table; and the other an isolation space with more bunks. As a rule only cases of minor illness or accident should be retained for the night at the post, serious cases (subject to enemy activity) being removed to hospital. One disease which was considered likely to have increased incidence as a result of shelter conditions was diphtheria, and immunization free of cost was being actively encouraged. The risks of air-borne infection might be reduced by spraying the air. Following upon researches at the National Institute for Medical Research a large-scale trial of antiseptic mist had been made at the Marble Arch tube station, where the mist was introduced into the plenum ventilating system, and as many stations had not this system a further trial in which the sprays producing the mist were operated by compressed air laid in the pipe along the wall of the platform had been made at the station at Bond Street. Much of the hand-spraying at present going on probably did not create a true bactericidal mist. Perhaps the shadow of Lister would note that something like his carbolic spray was again coming into its own. The wearing of masks against droplet infection had been carefully considered, and the principle had been accepted as sound and its practical application was being worked out.

Measures against lice-borne disease were being taken, including certain instructions to shelter marshals, but there was no evidence at present of any special spread of lice in shelters. Delousing stations were being made available, medical officers of health were being asked to consider what improvised measures might be brought into use, and an investigation of a new bactericidal powder was being made. Mosquitos had proved a source of trouble in the tubes, where in the older workings there were large collections of stagnant water in which the mosquitos bred. The species was *Culex molestus*, which, although not a disease-carrier, bit humans viciously. In the tubes, where practically summer temperatures always prevailed, the mosquitos had been obtaining plentiful blood meals from the shelterers and did not go into hibernation. With regard to latrines, he mentioned the installation of hoppered cylinders, in which the pails were emptied and, after closing a valve, the contents of the cylinder were driven up a pipe which discharged into a sewer. Finally he showed a graph of the shelter population of the tubes. The highest peak—186,000—was reached in September; the numbers had now fallen to about 100,000, but the reduction was mainly in the tube stations patronized by the more prosperous part of the sheltering community.

Dr. J. ALISON GLOVER, from the chair, said that the first and hardest fight was against overcrowding, which facilitated the transmission of every infectious and contagious disease. In the broadest sense its abatement was mainly a matter of administration. Public Enemy No. 2 was damp, which was of three kinds: percolation from sides, roof, and floor; condensation; and, most important of all, the respiratory miasma which overhung all crowded assemblies. There was much, however, to be thankful for. The *Blitz* started early in September, four months before the beginning of the epidemic season, which gave time not only for material improvement in the shelters but also for acclimatization to shelter conditions by the public and the mutual exchange of nasopharyngeal organisms with, it was to be hoped, some degree of non-specific immunity in the shelter population. In the last week for which he had figures the notifications for diphtheria and scarlet fever, though numbering more than in the corresponding week of 1939, when they were remarkably low, were still less numerous

than in 1938. Pneumonia notifications were at about the usual level. Casualties had been extraordinarily small in proportion to the weight of the air attack, and, although the work of the R.A.F. and the defence services must have the major credit, the fact that the shelters had stood up to splinters and blast much better than many anticipated must be taken into account.

The City of London

Dr. C. F. WITTI (medical officer, City of London) said that the majority of shelterers who came into the City nightly for refuge congregated in four deep tube stations. But there were a number of other shelters capable of accommodating over 500, and about one hundred in the "under 500" class. It was easy to talk about dispersal, but the difficulty of persuading people to leave an overcrowded deep tube station or tunnel for a more comfortable and airy basement had to be experienced. He had found surface shelters practically unused at night. It was a question of balancing the value of sleep and freedom from fear against the ill effects of vitiated air and risk of infection in crowded shelters. Compulsory evacuation of children was not practicable, and refusal to accept evacuation was seldom, if ever, due to the indifference of parents. At the same time, if a child's health was definitely suffering as a result of shelter life or endangered by the prevalence of epidemic disease in a shelter it should be possible to insist on evacuation or at least on transference to another shelter which, though not capable of standing up to a direct hit by a high-explosive bomb, was, perhaps for that very reason, more hygienic. If the shelter doctor could certify that the health of a child was obviously suffering, then removal might be enforced, for public sympathy would at once be on the side of the authorities. What about the disposal of cases of German measles and mumps occurring in the shelters? It was useless to suggest that these should be treated at home. If the isolation hospitals could not take them they must be kept in the medical aid posts and adjoining sick bays or transferred to shelters reserved for cases of minor illness. He was strongly in favour of the latter course.

It was difficult to believe that aerosols would be of much value for the disinfection of the air in the enormous spaces with which it was necessary to deal. The barrier method might be practicable and useful if they could concentrate in a certain part of the shelter cases liable to disseminate infection. It was useless to expect the installation everywhere of efficient mechanical ventilation; the best possible must be done by keeping open entrances and emergency exits and the use of electric fans. The heating of shelters might or might not be necessary. Deep underground shelters were usually too hot and humid. In one tunnel the temperature was never less than 70° F. at night. Smaller shelters with concrete floors and brick walls were usually too cold, yet on account of deficient ventilation heating could not be introduced. The shelterers must make adjustments by having more clothing or bedding.

The disposal of excreta was an enormous task. In the City, in the expectation that the shelterers would be mainly persons employed in offices or shops, an excellent type of chemical closet was installed in the proportion of one closet to every twenty-five persons in the day capacity. As the night capacity was from one-half to one-third of the day capacity there was an ample supply of conveniences, but he had been appalled at the way in which they had been abused by a certain section of the population. He had come to the conclusion that anything but the simplest appliance—a pail straddled by a wooden frame—was a waste of money, and in the pail he would have only a solution of some coal-tar disinfectant as a deodorant. He understood that the tube shelters were trying to work to a figure of one convenience for every seventy-five shelterers, but he doubted whether they would attain this. In the City it had been arranged to have the large public conveniences which were in close proximity to the tube stations open free all night long, but the results had been disappointing; the shelterers either would not take the trouble or were afraid to make the short journey outside. The only thing to do in the tube stations was to arrange for the closets to be kept under observation and emptied as necessary during the night. The installation of the pneumatic ejector systems would reduce the labour of the cleansing department.

There was no serious lice infestation as yet in the City, but he was afraid this might not continue to be the case. For homeless shelterers some opportunity for personal ablution must be provided, but for the washing of clothing and bedding shelterers must be referred to the districts in which their homes were situated. Bunks would have to be dealt with *in situ* by the application of liquid insecticides. In conclusion he begged critics of medical officers of health to realize the difficulty of the conditions under which they had been working.

General Discussion

Dr. S. DAVIDSON thought it a too optimistic view to expect that major epidemics would be escaped unless much more care was taken than at present. From his observation in the north-west of London brick shelters were almost unoccupied; people thought there was more protection in a deep shelter, and took the risk of contracting disease. It was also well to remember that eight or ten people in an Anderson shelter or fifty or sixty in a brick shelter were just as much overcrowded as 2,000 or 3,000 on a tube platform. The medical profession ought to concern itself with the provision of some form of bomb-proof shelter, possibly on the Haldane model (*British Medical Journal*, November 16, page 678). Dr. SINCLAIR-LOUTIT said that the fouling of lavatory accommodation was largely by young children, who found the adult-size chemical closet too big a problem. The provision of closets in the proportion of 1 in 25 if a fair proportion were small ones should make a great difference. As to the problem of the people who were ill but not in hospital, in a community of 50,000 there were roughly 1,400 cases of notifiable disease, of which only about 600 were sent to hospital. The population of the area he had in mind was now reduced to 38,000, but it still left a large number of persons with notifiable disease who had to be dealt with in their own homes or in the shelters. Among the same community there were about 350 young adults with a history of tuberculosis. Some plan ought to be found for the allocation of shelter space to these cases. Dr. UNDERWOOD (West Ham) did not believe that this policy of isolating tuberculous cases would meet with success. It would have to meet the psychological objection that people would refuse to declare themselves tuberculous by going into the special shelters. As in the City of London, so in his own borough of West Ham, there did not appear to be any evidence as yet of infestation in the shelters. Dr. A. BENJAMIN pleaded for more co-ordination between the engineering and medical departments of the local authorities. He related a case in which, in a shelter with seating accommodation for 180 people, exactly that number of bunks had been put in, resulting in overcrowding. The safe number was 132, but there was extraordinary delay in getting the surplus bunks removed. Dr. W. H. BRADLEY (Ministry of Health) described some work on the design of masks to prevent danger from droplet infection. The main difficulties in introducing light muslin masks in the shelters were the shyness of those whom it was hoped would use them, the absence of aesthetic appeal, the general indifference in the absence of any heavy infection, and the fact that the masks soon became moist and uncomfortable. It was fully realized that masks could be of great use in preventing direct projectile infection, but there were a number of practical difficulties in the way.

The Chairman of the Government Committee

LORD HORDER said that he had always regarded the shelter problem as an emergency one, rather like an acute if not fulminating disease. There would never be an ideal shelter. The problem had to be dealt with in opportunist fashion, and the difficulties removed so far as possible when they could not be got rid of entirely. From his experience of the framing of recommendations he felt strongly that these should be couched in positive, not negative, terms, also that they should be practicable, and, finally, that the psychological effect should be kept in mind. One must not be afraid of making suggestions which to the scientific ear might sound rather trivial. He thought it not incompatible for two policies to be pursued side by side; one of these was a long-term policy, in regard to which the refrain must be "Unload! Unload!" But it took a long time to "unload" these shelters, and therefore a short-term policy was also needed if the situation was

to be saved before the height of incidence of epidemic disease was upon us. He did not agree with one speaker who had suggested that doctors ought to concern themselves with the safety aspect of shelter policy—that is, safety against enemy action—but he reminded the audience that so far as fatal casualties were concerned it was a question of half-and-half anyway as between above-ground and under-ground shelters, and it was as well to bear in mind that some of the deep shelters were actually under military objectives, and for this reason the people might be safer on the surface.

There were some compensations in this "hideous emergency which has been thrust upon us." The research which had been stimulated would undoubtedly lead to valuable and permanent contributions to preventive medicine. It had also opened up a field for health education second to none in his experience. The shelterers were ready to listen to the advice given them and could be trusted to a large extent to carry out the instructions given by medical officers of health. Lord Horder added that he trembled every time he signed the final form of a recommendation, wondering what would be the reaction among his colleagues, and he was amazed at his "luck" so far in that his attention had not been drawn to any very obvious errors.

Dr. STOCK, in replying on the discussion, said that when school shelters were used as public shelters during the night very special care should be taken over the cleansing. The difficulty of cleansing bedding and clothing might be solved by mobile units. Further recommendations of the Horder Committee would be issued as a White Paper, and he thought would include advice on the wearing of masks, as to which valuable co-operation had been given by workers at the National Institute for Medical Research. One provision about bunking was that there must be at least two feet between the rows of bunks. Where, for some reason, this was impossible a partition had been devised for use between the head portions of adjacent bunks. He concluded by saying that there was one gleam of hope in the situation—namely, that the constitution of the "herd" in the public shelter might help to avert the disasters of the old epidemics. The "herd" was of much the same constitution as the ordinary population of London, but with a large number of the more susceptible members—namely, children—removed.

Correspondence

Unification of Shelter Control

SIR,—Your correspondent Dr. A. S. Jarman (December 21, p. 880) raises a point of central importance when he says that it is time we, as doctors, faced our social responsibilities. But the rest of his letter appears to be based on a misconception of the present situation. The shelter problem of London divides itself into two parts. The first part is that of providing reasonable safety from disease (as well as bombs) for that part of the population of this and other big cities who either live in or are able to reach districts where big buildings or such public works as tubes are available for use as shelters. To these, doctors and nurses have in many cases been appointed, bunks and canteen facilities provided, and to these shelters apply those improvements of which, in the B.B.C. and the Press, we have heard so much.

Quite different, however, is the problem presented by those areas of London and other cities where no such buildings exist, and where the district is composed of small dwellings, wharves, etc., incapable of providing large shelters. To talk of shelter doctors in relation to these is an absurdity, as no such shelters exist, and the fleeting moments of the visits of doctors and nurses, when they occur, can do no more than deal, and that unsatisfactorily, with pressing emergencies. In these areas the population is compelled to save itself as best it can with assistance from none but voluntary bodies, since nothing else is forthcoming. If it is argued that the central Government has delegated sufficient powers to local authorities to deal with all emergencies, the answer is that the multiplicity of these authorities, the apathy of many, and the extreme overwork of others almost wholly negate these powers. The problem is much greater than that of shelter diseases; it is that of securing the elementary necessities of living, hygiene, and sanitation, for an immense mass of our fellow citizens.

The areas and the people who inhabit them are the front line of the war, and as an army cannot act without a general and as the work of excellent relief units in the past has been ruined by an attempt to run them by committees, so the creation and organization of the measures to deal with this situation demand a directing mind with adequate resources and full authority to act. To urge arguments against this proposal because the term "dictator" has been used is to quibble about words. As I attempted to point out in a previous letter, the whole structure of local administration and the education of its officers is aimed at preventing the possibility of swift and co-ordinated action, and it is exactly that which the whole of Britain now urgently demands should happen in London. If the situation in the poorer areas of London and of the other bombed cities is to be met with energetic unified action, a single head who tackles the problem as a whole and acts directly through obstacles to the central objective is essential.

As a profession we are responsible to the people for their health. Is it not time that we roused ourselves, and as a body saw to it either that the central Government makes use of those powers we have delegated to it, or that by other and more direct means this objective is gained? We have in the British Medical Association the necessary instrument to collect information, disseminate it, and see that pressure is brought to bear on the authorities. Let us then take responsibility for our part of the war and "go to it."—I am, etc.,

London, W.1, Dec. 26. MARGARET LOWENFELD.

SIR,—Nearly every day for many years my work has taken me to the East End of London. I have therefore read with keen attention what the official representatives of the medical profession have permitted to appear about the shelter problem. It seems to me that the medical profession, whose individual devotion is unquestionable, has in one respect failed collectively to do its duty in the present crisis.

In addition to the natural obligations of community, there are other and forceful reasons why we, as a profession, should rise to this occasion, which is unique only in its urgency. The people living in industrial areas, particularly the East End of London, who always face circumstances with courage and heroism, have for the moment become an integral part of the front-line defences of this country. They are not just a group living within a national front; they are an integral part of it. It is for them that government exists. The Germans, who, since they planned it, have clearly visualized the nature of this war, know that civilian morale is a military objective. Now the medical profession who work among the poor know the appalling conditions which have always existed and which are intensified by the *Blitzkrieg*. Human beings deserving of comfort and security have as their constant lot overcrowding and anxiety. Now they live in conditions which approximate to the filth of the Middle Ages. This is particularly true of the smaller shelters which have not yet been brought under co-ordinated control. Such conditions, if perpetuated, must undermine that integration of character which we call morale.

It is therefore the natural duty of the medical profession to investigate and to make known the facts of the situation against whatever official opposition exists. I suggest that we should appoint a body whose business it is to amass information and to make it known to the general public together with its recommendations. Our position is happily still such that no Government could exist for long which ignored a report based, not on sectional and professional interests, but on the objective necessities of a social situation.

A large part of the solution of these problems depends on powers of control. In this connexion it is necessary to point out to some of your correspondents that there is a difference between a director appointed by a democracy and a dictator in the totalitarian sense. One is armed with plenary powers to carry out the intelligently conceived plans of a community, the other obtains power for its own sake by giving

a social sanction to the free expression of those wilder fantasies and deeper prejudices which it has been the business of nearly 2,000 years of civilization to tame and turn to useful social ends.—I am, etc.,

London, W.1, Dec. 26. H. W. S. WRIGHT.

Control of Lice in Shelters

SIR,—In your excellent leading article on "Unification of Shelter Control" (December 21, p. 873) you rightly call attention to the likelihood of the swift spread of lice-borne disease and indicate some of the measures to be adopted to prevent it. You omit, however, to mention the most important measure for preventing infestation—namely, the necessity for changing the clothes, especially the under-garments, at night and the regular washing of the underclothes. In peacetime body lice are rarely seen and are then found only in tramps and the inhabitants of common lodging-houses, who rarely change their underclothes. In the last war infestation with lice was high when the troops were compelled to wear their clothing for long periods at a time, but rapidly fell when they were living under more favourable conditions. Body lice live and breed in the underclothing, and, though nits may sometimes be found on the body hairs, this only occurs in heavily infested individuals. If the clothes are worn continuously temperature conditions are favourable for the rapid breeding of lice. If, on the other hand, the clothes are allowed to get cold for several hours each night, breeding is seriously interfered with and may even stop altogether. Washing of the garments further tends to reduce the chances of infestation. Cotton garments are as a matter of course boiled, and this will kill off all lice and nits. Unfortunately woollen garments cannot be boiled, but washing will mechanically remove the lice and most of the nits.

I venture to suggest that the vital importance of changing their clothes at night and of the regular washing of their garments should be impressed on all those who use shelters. The prevention of infestation is primarily a matter for each member of the community and not for the public authorities, and it is important that the public should be informed of this without delay and in no uncertain manner. On the public authorities rests the responsibility of dealing with already infested persons and of providing the necessary clothing and washing arrangements for those who have lost their homes.—I am, etc.,

London, W.1, Dec. 23. A. M. H. GRAY.

Removal of Nits

SIR,—It is stated in a note attached to the memorandum dealing with drugs used in dermatological practice drawn up by the Therapeutic Requirements Committee of the Medical Research Council (December 7, p. 795) that ". . . the nits can then be removed by a fine comb after the application of vinegar or dilute acetic acid." On the other hand, in an article entitled "The Control of Lice," by Prof. P. A. Buxton (November 2, p. 603), we read: "The legend that vinegar or acetic acid loosens nits and enables them to be combed out was disproved twenty-five years ago: it dies hard."

It seems a pity that a memorandum containing recommendations which are of interest to the majority of doctors should help to keep alive this legend.—I am, etc.,

Hornchurch, Essex, Dec. 27. PATRICK X. O'DWYER.

Air-raid Casualty Services

SIR,—Having been a member of both a first-aid post and a stretcher party since September, 1939, I was extremely interested in the editorial "Air-raid Casualties" (November 23, p. 716) and am sorry that it has not evoked more comment.

The article contains references to the work of the stretcher parties and of their difficulties in exercising proper judgment in the classification of casualties according to immediate need for first-aid treatment and priority of removal to hospital or F.A.P. under the adverse conditions of darkness, bombs, and the necessity for speed. Such references are in my experience (and that of my colleagues) quite true. Stretcher parties for the most part are quite unable to carry out the "pre-blitz" plans assigned to them, in which it was expected that they would be able to sort out, treat, and despatch casualties in a certain prescribed manner so that every injured person might be sent to the place at which the appropriate treatment necessary could be given at the earliest possible moment. As you state, the ghastly appearance of many, yet whose injuries are but minor, does suggest a hospital case, whereas treatment could be more conveniently given at a first-aid post. As a result of the disability to differentiate, almost all cases are sent straight to hospital, with little or no attempt at classification or priority of removal, while the first-aid posts and mobile units are used only to a very minor extent.

The need for accuracy in the sorting of cases according to immediate need for first-aid treatment and priority of removal, difficult though it is, is so important for the injured and the smooth working of the plans for their treatment that some steps must surely be taken to remedy the present position. A much greater use should be made of the medical profession; a doctor ought to be present at each incident if at all possible; as it is, I believe that many practitioners attend voluntarily and unofficially. The mobile units could also be used more frequently if their number were increased, the individual personnel of each reduced, and their equipment simplified. They could be sent out to each incident to return if not wanted or to remain and act as a classification centre if needed.

Even then the problem would not be solved, and the success of the present plans will still remain in large measure with the stretcher parties, on whom the main burden will still rest. In my opinion it is not possible to expect the stretcher parties to do their work efficiently unless more care is taken in the selection of personnel and their training is adequate to overcome the difficulties under which they are called to exercise their judgment in dealing with all types of injuries. Not the least of the errors of local A.R.P. organization has been the herding together of all types and conditions of men into stretcher parties without any real attempt at selection in accordance with ability, giving them eight lectures in first aid (in most cases from the British Red Cross or St. John Ambulance manuals, which have little relation to air-raid casualties), and then expecting that they can exercise a judgment that many medical men would hesitate to give under the conditions encountered.

I am sure that a much greater degree of efficiency, and a much closer approach to the intentions of those who planned the work of stretcher parties, could be obtained by a carefully planned selection of personnel into two sections—that is, stretcher bearers and first-aid workers, with special appropriate training for each based upon the experience of the past few months.

The first-aid section, chosen for their ability to make use, under adverse circumstances, of special tuition, would be trained to exercise to a much greater degree than at present possible that judgment so essential in rendering the most appropriate form of first aid, the initiation of anti-shock treatment, and in determining the order of removal and proper destination of casualties. Freed from the need of having to do any transporting, which would be done by the bearers, they would have more time to do the important work and to do that more effectively and speedily than is possible by less-trained workers, especially if they can work in co-operation with a doctor. It has to be remembered that, even if a doctor is present, his work is seriously handicapped unless the stretcher parties are highly trained, for he must rely to a great extent upon their judgment in either bringing the injured to him or indicating the position of those who need his services most; and any errors may lead to his attending to certain cases while someone else is bleeding to death a few yards away.

The stretcher bearers should be specially equipped and trained in the removal of all types of injury from wrecked houses and over debris, and I must emphasize that training in this respect still leaves much to be desired (*vide* many letters on the removal of the injured and shock), probably due to the fairly constant change of personnel owing to call-up for military service. There are plenty of opportunities for lifelike training among air-raid ruins. There is an appalling waste of good material in the stretcher parties as at present organized. Almost any doctor attached to or engaged in lecturing to them will bear out this statement that there are large numbers of the personnel who could, with suitable train-

ing, become extremely valuable assets in the difficult and responsible tasks of the stretcher parties, and I feel sure that the answer to many of the points raised in your article will, in part, be met by the suggestion put forward. No one would dare to question the courage or resourcefulness of the stretcher parties, but I can assure you that not many of them are satisfied with the present position, in which the most and best that they can do is to hurry all casualties off to hospital. Most of them would welcome being placed into the category for which they were best suited and given a training that would make them more efficient and able to render the assistance that they want to be capable of giving.

I enclose my name and address, not for publication, in case this letter be misunderstood and taken to be a criticism of the Borough Council that employs me.—I am, etc.,

Dec. 23. F.A.P. AND S.P.

London Air Raids

SIR,—There has been such an interesting response, both in your columns and in personal letters, to my letter (November 9, p. 643), that I am tempted into print again. My experience has been in an outer borough in the London region. We have in this area few factories and few high buildings: we have received probably between 60% and 80% of London's average damage in terms of tons of bombs per square mile.

Most of the control room duties of the medical officer of health can safely be delegated to a well-trained lay deputy, provided the M.O.H. can be contacted within a few minutes (which is possible via a wardens' post system wherever in the area he may go). It therefore seems proper for the medical officer to go out to any incident with numerous or trapped casualties without waiting to be sent for. He is likely to be valuable as a senior officer or as a doctor, or both. After bombs have fallen it should often be possible to decide soon and reasonably accurately which incident is more suitable for the mobile unit (or for the unit doctor with one or two assistants) and which for the M.O.H. In our own case geography often gives the answer. The control centre and mobile unit are near opposite ends of an awkwardly-shaped administrative area.

Several correspondents visualized the exact difficulty of giving morphine injections and had probably experienced it. It is often essential to prepare and give an injection in a really awkward position with one hand. The tubunic ampoule by Roche is an elegant and adequate answer. Alternatively a 1-c.cm. syringe with its piston ring intact (and therefore no tendency to empty under the force of gravity) can be stowed temporarily in one of the narrow cylindrical tins commonly used for diphtheria swabs, and put in a buttoned pocket.

One hears that in certain areas stretcher party men "wait on the pavement for their casualties" and will undertake no other activities of any sort. As regards air-raid action, I am convinced that the stretcher party leader, like the doctor, should be encouraged to reached trapped casualties at the first moment he can be of any use without dangerously obstructing the rescue parties. In the absence of raids and even during daytime "alerts" we have now received an official blessing for a most desirable practice—the assistance by up to about 50% of the stretcher party strength in clearance and salvage work. Most of the men are glad to do this once they realize its value, and I think the service would be improved if this work were put on a compulsory basis and grousers, if any, dismissed. One of the main difficulties in maintaining morale has been and always will be the provision of sufficient worth-while "fatigues." An unnecessarily large amount of floor scrubbing is better than everlasting ping-pong and darts, but it is a poor substitute for a proper day's work.

So far as I can ascertain, certain authorities accept and others refuse altogether the conscientious objectors sent to them by the tribunals. As tolerance is one of the things we happen to be fighting for, they are accepted here if they live in the area and vacancies exist. I am glad to be able to say that this has not led to difficulties with other personnel.

A large number of civil defence volunteers, full- and part-time, were persuaded, or ordered, rather against their own wishes, not to join the Home Guard on the ground that they could not properly undertake both responsibilities. They now look with envious eyes at the warm overcoats, boots, etc., of the H.G. (and, incidentally, the A.F.S.), and wonder why they are expected to undertake their own onerous and often dirty duties in their own clothing, or, at best, in an aged boiler suit and, with luck, a pair of gum-boots.

The following is quoted merely as one of many amusing but rather appalling examples of the results of divided control. We received verbal instructions many months ago that in stretcher party depots there ought to be an individual issue of three blankets per man. Recently I was able to obtain documentary backing for demanding this reasonable issue (but not, needless to say, the blankets). I have also received an instruction that the proper issue of blankets for a first-aid post is three blankets per bed for 75% of personnel on duty—that is, in our case 37½% of the proper issue per man for a depot. It is, or rather ought to be, surprising that the Ministry of Health is the more conservative in a matter of this kind.—I am, etc.,

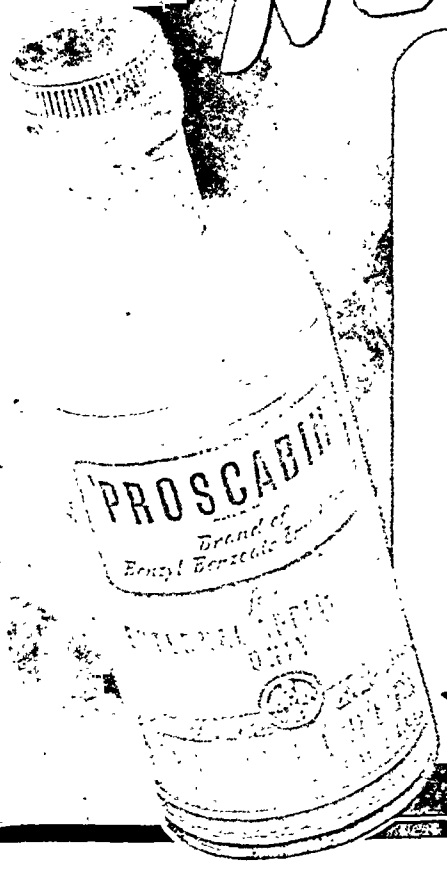
Dec. 23. E. B. GROGONO.

The Mobile Unit in Action

SIR,—I have read with great interest Dr. J. J. Cremin's letter on the mobile unit (December 14, p. 847), and I endorse heartily his views, which I have held since the inception of the mobile unit. Quoting from the Ministry's Circular 1789: "The intention in using mobile units is partly to enable a complete first-aid medical unit to proceed to the actual site, there to set up, either in the shelter of any convenient building, or even, if the weather is fine, in the open air, and partly to reinforce the fixed aid posts. It is not proposed that first aid should be carried out inside these vehicles." It is exactly in these respects that the mobile unit will often fail in its object, as it failed in Dr. Cremin's case.

Trueta, in an address to the Royal Society of Medicine (*Proc. roy. Soc. Med.*, 1939, **33**, No. 1) stated: "Sometimes hindrance is due to defects in the organization itself, as happened in Barcelona when emergency treatment posts were set up inside ambulances." Again "... after the tragic experience of Barcelona I maintain that the immediate intervention of the surgeon in hospital is the only useful form of first aid other than the application of a tourniquet to the limb which bleeds excessively, and this can be applied by the ambulance man. The application of a splint, bandage, or other form of first aid has been shown in my city not only to be useless but actually harmful, because it always delays the surgical treatment."

Personally I have seen the mobile unit at practice in co-operation with the various A.R.P. services in mock raids, and I am of the opinion that they are a waste of time and personnel. I feel that it would be far better to employ a larger personnel of trained stretcher-bearers, who could work swiftly in co-operation with an adequate first-aid party, rapidly transferring cases to a fleet of speedy ambulances, which would proceed forthwith to hospital. This active body of first-aid workers under the direction of their squad leaders would be responsible to one medical officer and nurse, who, armed with morphine, should have reached the scene of activity in a small fast car, being summoned from the control room at the earliest possible moment.



Finally, I agree that it is reprehensible for "key" medical and nursing personnel to take part in the mobile unit. I know of one hospital where the medical officer in charge would be obliged to go out with the mobile unit, attend and supervise casualties, return to hospital to supervise admissions, etc., and then operate, being one of the few surgeons available in that district.—I am, etc.,

Barnsley, Dec. 18. ISAAC ROSE.

SIR,—A letter from Dr. J. J. Cremin (December 14, p. 847) expresses exactly the opinion we have come to from our experiences in this city. On the occasion of a recent air raid instructions were given from A.R.P. Main Control for one of our mobile posts to proceed to the scene of an occurrence where we were led to presume the presence of a considerable number of casualties. However, when the mobile post reached the scene the few casualties that had occurred were already cleared away to hospital. The second mobile post was sent out to the scene of another occurrence where one of our aiding

depots had been destroyed. Certainly there was no lack of casualties in this case, but the light from burning buildings proved, as it so often does, a target for further bombs, with the result that the mobile post was burned out and though there were no casualties among the personnel the unit was rendered useless. If they had been stationed at a fixed post I am of the opinion that their services would have been more valuable.

As a result of our experience we have decided not to replace the burned-out mobile post, but to disperse the personnel to strengthen those fixed posts where their presence is most needed. The mobile post is doubtless most valuable in a county to visit isolated villages, but it is difficult to envisage any situation in a city where it can prove of more value than the ordinary fixed post.—I am, etc.,

Leicester, Dec. 18. F. K. MACDONALD, Medical Officer of Health

Epidemic Influenza

SIR,—Dr. William Hartston (December 21, p. 878) signifies with quotation marks a reminiscence of something he has heard me say, which was, probably, the epigram that when we don't know what we are talking about and don't care whether what we say is true or not we are talking pure mathematics. I dare say I explained what it meant. The great mathematician who originated it meant that starting from *any* axioms and postulates not self-contradictory, the task of the mathematical logician was to deduce consequences which were *consistent*; whether the postulates were true and the consequences had any "real" meaning was beside the mark. Why Dr. Hartston thinks this is a sneer at mathematics or what it has to do with forecasting epidemics, Heaven only knows.—I am, etc.,

Loughton, Dec. 23. MAJOR GREENWOOD

Convulsion Therapy in the Out-patient Department

SIR,—Dr. E. Cunningham Dax (December 21, p. 878) tells us that it was with foreboding that he anticipated the use of electrical convulsant therapy under out-patient conditions. I too may reveal the fact that I foresaw the kind of criticism that an account of the treatment would call forth; and, moreover, I prophesied that it would come from an experienced institutional psychiatrist.

Dr. Dax's letter, although it appears to deal solely with the question of electrical convulsant therapy, in reality reveals the wide gulf which, alas!, still divides psychiatry as it is understood and practised in the teaching hospital and consulting-room and institutional (asylum) psychiatry. The institutional psychiatrist, in the course of time, is apt to forget what the symptomatology and reaction-forms of really early mental disorder are like, and to think in terms of types rather than of individuals (Dr. Dax's own hospital caters for over 2,300 patients, I believe). By the time that the patient has been compelled to enter a mental hospital either as a voluntary or as a certified patient, his mental disorder is already far advanced; and within a few weeks of the patient's admission the psychiatric picture has changed: something has been added to his original mental disorder—the "asylum psychosis." Further, I believe that the consultant psychiatrist sees *in the psychiatric department of a general hospital and* in his consulting-room many patients whose mental disorders are even less advanced than is the case with those who find their way to the out-patient clinics associated with many of the more progressive mental hospitals.

The majority of cases of *early* mental disorder can be, should be, and in point of fact are, treated in out-patient clinics, consulting-rooms, and private nursing homes; any form of treatment which shows promise of being able to "stop the rot" or alleviate symptoms, thus reducing the mental hospital population, should be given a fair trial under out-patient conditions. Consider, for example, recurrent endogenous melancholia of the manic-depressive type: my mental hospital colleagues tell me that it is a relatively rare disorder, whereas I see several fresh cases a week. The reason is that only a small proportion find their way into the mental hospitals. Every such patient is a suicidal risk, admittedly; but it is a risk that every consultant psychiatrist must be prepared to take in the appropriate circumstances. I myself have been fortunate enough never to have incurred the loss by suicide of a depressive patient under my care, either in his own home or in a nursing home.

Dr. Dax's statement—"It seems unlikely that as good results will be given by treatment in the environment where the patient's illness began as when the patient is separated from his home surroundings"—is far too sweeping. In many cases of mild or early psychosis the individual attention which can be given by devoted relatives to the patient under the guidance of the consultant psychiatrist is infinitely preferable to the impersonal handling of a patient by mental nurses, trained or under training, in the 2,000-bed mental hospital.

Now to deal *seriatim* with some more points raised by Dr. Dax:

1. If the patients for treatment by electrical convulsion therapy under out-patient conditions are selected with care and skill, and their reactions studied week by week, none of the accidents mentioned in the second paragraph of Drs. Dax's letter need occur.

2. "Half to one hour is too short a time for rest following a fit": The fact remains that nearly all the patients so far treated have rested or slept for half an hour or so, and have then expressed themselves as ready and anxious to return home. The majority sleep unusually well the night following *the fit. In my experience the same is true of many cases of* idiopathic epilepsy. I agree that the same technique cannot apply in the case of chemically induced convulsions.

3. I cannot agree that the retention of clothing (with the exception, of course, of tight corsets) in any way restricts free movement. The amount of restraint employed in my department is merely sufficient to prevent the patient from falling off the couch or from injuring himself. It is an interesting fact that with the electrical apparatus the convulsions are very rarely so violent as those produced with cardiazol. So far, none of my patients has sustained a fracture or dislocation. If Dr. Dax includes under fractures those symptomless cracks in the bodies of vertebrae which are only discoverable by *x* rays, this last statement may be challenged: for I have not looked for them. I think it is mischievous that such fractures should be considered under the heading of "risks" when a patient's mental health is in question.

4. "The general hospital is not the place for even mild, uncomplicated mental illness." I cannot concur. I look forward to the time when every teaching hospital will have its properly equipped and adequately staffed psychopathic wards. Such is the laudable intention of St. George's Hospital, for instance, when it moves into new premises.

Finally, I should like to assure Dr. Dax that "the patient's welfare is the only consideration"—so much so that I am doing my utmost to save as many patients as possible from our overcrowded under-staffed wartime mental hospitals, even at the risk of a few psychiatric "accidents" of a kind which so far fortunately have not occurred.—I am, etc.,

London, W.1, Dec. 21. E. B. STRAUSS.

Haemorrhagic States with Snake Venom and Lecithin

SIR,—We have read with much interest the paper by Prof. L. J. Witts and Miss Felicity C. G. Hobson (December 21, p. 862). We have ourselves been carrying out experiments on closely related lines, the results of which are at present being prepared for publication. It is hoped that a full account of the work will be published in the *Journal*. Our results confirm the observation of Witts and Hobson that lecithin potentiates the action of Russell viper venom in the Quick test for *prothrombin. When used with brain extract lecithin produces* only a very slight decrease in the coagulation time. We have also been unable to determine any important accelerating effect in conditions of marked prothrombin deficiency. Our attention was originally directed to this problem by the observation of one of us (A. C.) that the presence of slight haemolysis in the plasma was associated with a decreased coagulation time as determined by Quick's method. The important point brought out by our own work is that the effect of slight haemolysis of the blood is more marked than the addition of lecithin. It is evidently not due to the presence of

haemoglobin in the plasma, since the addition of solutions of "crystalline haemoglobin" has no effect. We consider that it may possibly be explained by the liberation of lecithin from the envelopes of ruptured erythrocytes. Since the effect of even slight haemolysis may be very marked it is obviously of great importance that specimens of blood for prothrombin determinations shall be absolutely free from haemolysis.—We are, etc.,

Clinical Laboratories, Royal Infirmary, Edinburgh, Dec. 24. ANDREW CROSBIE. HAROLD SCARBOROUGH.

Recurrent Peptic Perforation

SIR,—The interesting account of a case of "recurrent peptic perforation" by Mr. Gavin Milroy (December 21, p. 868) brings to mind a similar experience of my own which occurred recently.

A man aged 53, was twice admitted to hospital as an emergency case and twice operated on for a perforated gastric ulcer. This happened within the space of one year and ten months. At the first operation the ulcer found was pre-pyloric in position and the suturing of the perforation so stenosed the lumen of the viscus that, contrary to my usual practice, I would have performed a gastro-enterostomy as well had the patient's general condition allowed of it. In the end things turned out satisfactorily without this additional procedure, and an *x*-ray report one month after operation stated "that there was no obstruction or delay in the passage of the meal into the jejunum." I had, nevertheless, intended to watch his further progress.

At the second operation a small perforation of a new ulcer high up along the lesser curvature was found. This was sutured with ease and the peritoneum drained as before. In both instances there was a short history of indigestion of seven days only before the perforations occurred. The patient was operated on twelve hours and two hours respectively after the onset, and on both occasions convalescence was uneventful. The patient was the sort of man not to seek medical aid until seriously ill, and despite advice did not return after his first experience. A further point of interest is that his brother died of "perforated duodenal ulcer" twelve months before the date of the patient's first attack.—I am, etc.,

London, E.3, Dec. 26. J. R. M. WHIGHAM.

Euthanasia

SIR,—Dr. Killick Millard (December 21, p. 881) is naturally pleased to announce the number of persons whom he has persuaded to support his campaign for the legislative sanction of voluntary euthanasia. Presented from the sentimental aspect his case has a quality of sympathetic appeal. Adhesion to it, however, has little value unless consideration has been given to the social and professional objections that have been advanced by representative speakers on behalf of the medical profession, and to state these objections is not the affair of Dr. Millard's organization. In these circumstances the mere quotation of numbers of adherents may possess some advertising value but is little likely to impress opinion within the medical profession.

Should the State authorize the practice of voluntary euthanasia it must needs appoint executive officers to administer the fatal draught. Doctors, whose purpose it is not to destroy life but to relieve suffering, may reasonably refuse to have this task imposed on them. I suggest that Dr. Millard's supporters, as a test of their convictions, might appropriately be asked whether they are willing personally to volunteer for this painful service. He is but a feeble disciple whose record is one of faith without works.—I am, etc.,

Hove, Dec. 23. C. O. HAWTHORNE.

Some Points about Stretchers

SIR,—I notice with concern that District Councils tend to use A.R.P. fitments even in their "non-A.R.P." ambulances. This matter needs serious consideration.

The discomfort of the A.R.P. stretcher may be remedied by covering it with a thick mattress of porous rubber, and the sharp upward projections of the stretcher carrier fitments, so apt to cause injury, can be cut down or encased in wood.

Other troubles, however, must arise, since the time-honoured comfortable canvas stretchers will usually not fit the A.R.P. stretcher carrier guides. The Army stretcher (6 feet between runners) will go on only if the stretcher carrier is fitted sufficiently far aft in the ambulance. The St. John stretcher, with its narrower width, 22 inches or less between runners, will fall through if placed on the guides, and this same serious criticism applies in the case of railway ambulance stretchers (L.M.S. was tried) and the police stretcher. Wider angle-iron guides would be required to take these stretchers, and it would be well to be prepared for what might be an awkward situation.

Is it sound policy, however, to throw over the product of generations of stretcher experience for the sake of a very hypothetical facility in gas decontamination? For the latter two years of the last war mustard gas shelling was practically an everyday experience to regimental medical officers. I cannot recollect that decontamination of stretchers was other than a minor preoccupation.—I am, etc.,

Denbigh, Dec. 22. D. G. DUFF.

Treatment of Burns

SIR,—Surely what we want to teach the public and first-aid workers in regard to the treatment of burns is something simple, easily obtained and easily applied, and efficacious. The controversy raging at present is only adding to confusion. Tannic acid and/or silver nitrate, the treatment *par excellence*, is not only difficult to apply in ordinary circumstances, but also dangerous in unskilled hands. In hospital it is the ideal treatment, but in a back kitchen or even in a first-aid post with a rush of casualties the detail calls for time, experience, and special facilities.

My experience has taught me to follow a strict course:

(1) Treat the shock, no matter how slight the injury may seem. For first aiders and others in that category this is best done by: (*a*) Laying the patient flat. (*b*) Application of warmth (blankets, hot-water bottles, etc). (*c*) Fluids *ad lib.*, even if it is ordinary water (lukewarm). No attempt is to be made to deal with the burn until the general condition has improved. The doctor must give morphine, or tinct. opii (according to age), or pot. brom. (for small babies).

(2) Cover the burn with a piece of dry lint and bandage lightly.

(3) Remove to skilled attention.

The special treatment I use and advocate after (1) is to soak a piece of gauze (or lint) in a solution of flavine and paraffin 1 in 1,000. *Do not squeeze*, and apply to the burn and bandage lightly. I have had excellent results in all degrees of burns from this line of treatment. The flavine and paraffin immediately soothes the injured area and the raw nerve endings, thus preventing further shock. The colder the solution the quicker the relief, and no increase of shock; in fact, I usually pour it on and cover with gauze. I have not yet seen a case of sepsis following treatment with flavine and paraffin. The solution reduces greatly the chances of secondary shock; it is easy to apply and it is cheap. I usually repeat the dressing once in twenty-four hours, dress once daily for three days, then once every two or three days, depending on the amount of inflammation present.

Blisters are *not* opened until twenty-four hours after the application of the first dressing. Primary and secondary shock have by then been overcome, and the antiseptic value of the solution has had time to affect the area and surrounding skin. The blisters, when opened, are done so under as aseptic conditions as possible. Once the inflammation has subsided elastoplast strips complete the granulation process. I have found that the combination of flavine and paraffin followed by elastoplast greatly reduces skin contracture.

Where the burn has been of extreme severity and/or important locale the case is referred to hospital after treatment of primary shock. I still apply flavine and paraffin to the burn because of the immediate relief locally. Cleansing of the area in hospital will, I presume, be conducted under an anaesthetic, and the journey to the hospital is rendered as free from pain as possible.—I am, etc.,

Brighton, Dec. 18. LEONARD A. DE DOMBAL.

First Hospital for Diseases of Women

SIR,—I read with great interest the excellent article on J. Marion Sims by Prof. Chassar Moir (December 7, p. 774). In it he concludes that the hospital founded by Sims in New York in 1855 was "the first hospital, in the modern sense of the word, to be devoted to the treatment of diseases of women, and it thus marks the origin and recognition of gynaecology as a medical specialty in its own right." The credit for the earlier establishment of an institution for the treatment and study of gynaecology must go to London and in particular to Dr. Protheroe Smith. In 1842 I quote from the early records of the Hospital for Women, Soho Square: "the expediency of having a hospital for the exclusive reception and treatment of poor women afflicted with diseases peculiar to their sex . . . having been brought under the consideration of several gentlemen resident in London by a member of the medical profession . . . a provisional committee of noblemen and gentlemen was formed . . . month of August of that year." The hospital thus founded was opened in Red Lion Square on January 25, 1843. Forty years later the Hospital for Women moved to Soho Square, where it still stands, and is thus the oldest hospital in the world to be devoted exclusively to gynaecology.—I am, etc.,

London, W.1, Dec. 20 W. R. WISEMAN.

Treatment of Stomatitis in Children

SIR,—I find that the following mixture is effective in the treatment of stomatitis in infants; both the local lesions and the pyrexia subside in three or four days. I think the fruit mixture works fairly well even if it is spat out. For a child of 3:

R Pot. iodid. ... ... gr. j
Liq. hydrarg. perchlor. ... ... m viijss
Glycerini ... ... m x
Aq. fontis ... ... ad fl. dr. j
q.q.h.

The local treatment described in the annotation in the *Journal* of December 14 (p. 838) is extremely difficult to do for refractory infants. In adults and older children I have found local treatment with liq. arsenicalis or sol. acriflavine 1 in 1,000 effective.—I am, etc.,

Coventry, Dec. 18 DONALD FROST.

Tetanus and the Need for Prophylaxis

SIR,—Perusal of the correspondence on the use of tetanus antitoxin leads me to the surprising deduction that in the past it has not been in regular use as a prophylactic in all London hospitals. For many years every casualty with an open wound admitted to the wards of the Northampton General Hospital has received tetanus antitoxin on admission. During this period a number of cases of tetanus, mostly fatal, have been admitted, but I have never seen the disease arise in a patient who has been given antitoxin. In 1918 a soldier fell from his bicycle and sustained a slight wound of the leg. He was admitted to an auxiliary hospital, developed tetanus, and died. The house-surgeon, when questioned, stated that the man had not been given the usual dose of antitoxin because he was not suffering from a gun-shot wound. It appears that the point of view of that house-surgeon is not so unusual as I thought.—I am, etc.,

Northampton, Dec. 19. *C. C. HOLMAN.*

SIR,—Messrs. W. McAdam Eccles and Frank Coleman (December 14, p. 846) seek to elicit information as to the use of tetanus antitoxin in England and Wales for casualties with open wounds. This question and that of Dr. H. H. Sanguinetti (November 23, p. 720) as to the occurrence of tetanus from London soil and the advisability of giving tetanus antitoxin in all cases of open cuts or wounds where there is a possibility of contamination by soil are answered by Drs. V. H. Addison, A. R. Nettleton, and J. E. G. Earle (December 14, p. 847).

I was attached in the autumn of 1914 to a French hospital at Dinard which received in special wards all cases of tetanus coming from the French Army from the battlefields along the River Marne, where, as stated, the soil is much cultivated and market gardens for Paris existed. These cases of tetanus had received no tetanus antitoxin, and, indeed, treatment had been unavoidably delayed. Similarly, in September, 1914, several, mostly fatal, cases of tetanus were treated in No. 1 General Hospital at St. Nazaire in Brittany, where my wife was nursing, among the British troops after their retreat from Mons.

Tetanus is truly a "horrible disaster," but it need hardly occur, for I can confirm Messrs. McAdam Eccles and Coleman's statement that a "dramatic lessening" of cases and of the death rate was brought about by the introduction of tetanus antitoxin, at any rate over-seas, during 1914 to 1920. Hence I suggest that there is past and present evidence to warrant that the instructions in Section 15 of E.M.S. Memorandum No. 4 for England and Wales that "tetanus antitoxin *should* be given to all casualties with open wounds" should be strongly advised and be carried out when the possibility of contamination of such cuts or wounds by soil exists.—I am, etc.,

Woking, Dec. 16 F. G. BUSHNELL.

Dangers of Sulphapyridine

SIR,—I cannot agree with Dr. W. F. Corfield in his statement (November 16, p. 682) that sulphapyridine soluble can be given into the gluteal muscles without any particular precautions. If given subcutaneously ulceration of the skin with a persistent sinus results. If given deeply there is a grave danger that one of the larger branches of the sciatic nerves is involved. I have seen six cases of foot-drop with varying degrees of anaesthesia result from this accident. Although most cases showed varying degrees of recovery, often with intensely painful muscles, one case showed almost complete foot-drop after three months. Another case developed gluteal paresis, so that he was unable to fix the pelvis three months after receiving the injection. Children seem particularly liable to develop gluteal weakness owing to the motor nerve being partially or completely destroyed. So long as the affected muscle shows a response to faradism a nearly complete recovery appears to take place. Unless there is a good and plentiful blood supply to the part injected no absorption takes place, so that destruction of the near-by tissue begins. Microscopically, at first, there is what appears to be a hyalinization of the cells where the solution has reached. If the blood supply is good the fluid is absorbed and the cells ultimately recover, but if the blood supply is bad the cells undergo necrosis and later fibrosis.

I consider that 3 c.cm. is the maximum amount that should ever be used in one place at one time, because the body is unable to absorb more, and instead of its being absorbed the tissues are destroyed. Three c.cm. is probably a dangerous amount to give to a child. Intramuscular sulphapyridine should, I think, only be given in an emergency while arrangements are made for giving it by the intravenous route if for any reason the patient cannot absorb the drug from the stomach or if a high concentration is required. Though crippling dangers are at present rare, this is no excuse for not knowing that they may occur, especially when with the increasing use of the intramuscular route in inexperienced hands they will become more common.—I am, etc.,

A. W. FRANKLAND,
Nov. 22. Lieutenant, R.A.M.C.

Rationalization of the British Drug Industry

SIR,—Your annotation with the above title (December 21, p. 875) really deals with two subjects—the nomenclature of new drugs and a proposal for rationaliation of the drug industry by nationalization or by the formation of a British version of the I.G.F. To advocate nationalization is a trifle dangerous if the British Medical Association is to continue to oppose application of the same principle to the medical profession. The idea of a financial merger is being freely canvassed at the present time by industrial interests that hope to control the combine.

But, leaving the realms of high finance and speaking as a member of the medical profession, I believe that most doctors will agree that the multiplication of proprietary synonyms is to be deplored: and the B.M.A. will have solid support for

any steps they may take to put a stop to this unfortunate practice. On the other hand there may be many in the profession who will regard as ungenerous the fact that you give a German firm credit for the drugs they gave the world, while you suppress the name of the only British firm that can claim to be associated with the production of "sulphapyridine, sulphathiazole, and the new trypanosomicidal drugs of the guanidine and amidine class."

The *Journal* has consistently preferred to use the American term "sulphapyridine" to describe the drug discovered by a British firm of manufacturing chemists, and yet the *Journal* uses the name "Bayer 205." Whatever the reason for such discrimination, I am satisfied that the medical profession as a whole will prefer to remember the name of the firm which gave the world M & B 693.—I am, etc.,

May and Baker, Ltd.,
Dagenham, Dec. 27. ROBERT FORGAN.

Obituary

RAYMOND PEARL, Ph.D., LL.D.

Professor of Biology, Johns Hopkins University

We regret to announce the death of Prof. Raymond Pearl, who since 1930 had been Professor of Biology, School of Hygiene, Johns Hopkins University.

Raymond Pearl was born at Farmington, New Hampshire, U.S.A., in 1879. After taking his A.B. at Dartmouth College in 1899 he worked in many universities, including the University of Leipzig and University College, London, where he was from 1905 to 1906. From 1918 to 1925 he was professor of biometry and vital statistics in the School of Hygiene, Johns Hopkins University, where he was also professor of biology in the School of Medicine and director of the Institute of Biological Research. He was Heath Clark Lecturer at the University of London in 1937. He made numerous contributions to scientific literature, and was editor of *Human Biology*. We are indebted to Professor Major Greenwood, F.R.S., for the following appreciation.

A letter from Baltimore brings me the news of the death from coronary thrombosis of Raymond Pearl. His many friends in England will find it hard to realize the extinction of that buoyant personality, the very image of physical and mental vigour, a man of 61 who could have passed for 40.

Pearl was a pupil of Karl Pearson in 1905–6. His earliest work was biometric in the strict sense of the term—a study of paramoecium—and followed by an equally careful and laborious study of human brain weights. Then he did important work on the genetics of poultry in Maine. I first met him in 1917 or 1918, when he was in England as a member of Mr. Hoover's staff. In 1918 he became the first professor of biometry and vital statistics in Johns Hopkins University; later he exchanged this post for the chair of experimental biology. Pearl was primarily a biologist, but his cultural background was wide; he knew and loved the best books in ancient and modern languages, and in a charming little book (*To Begin With*) tried to humanize the outlook of young students of science.

It is common form in literary circles to sneer at the literary crudeness of scientific writers. If we conveniently ignore such men as Huxley, Tindall, Helmholtz, and Karl Pearson, there is enough truth in the generalization to sting. Pearl had command of an admirable prose style informed by wide reading and a sense of humour. As the demand for books and papers is much greater in America than here he was tempted to write very often, and so led occasionally to overstatement, to the delight of pedants—the kind of people who rejoice over a mistake in Macaulay. Those who have had, and resisted, the same temptation may cast stones. His output was so large that even in a formal notice a good deal would not be mentioned; in a personal tribute it is permissible to speak only of what seemed to the writer both characteristic and first-rate. I should give first rank among his books to *The Rate of Living*, published in 1928; it is a small book but epitomizes the work of years. Pearl first used the method of experimenting on populations—now familiarized by the mouse colonies of experimental epidemiologists—and worked on the fruit fly *Drosophila*. He was the first biologist to compute from adequate data orders of dying out, or life tables, for any animal but man. Pearl pointed out that if we wished to study the general relation of age and mortality we should begin at the age at which mortality is at a minimum—namely, after the troubles of immaturity have been surmounted (in man at about age 12, in insects at the imaginal stage). Pearl's work is open to minor technical objections, but is of great interest, and will, one hopes, be continued. In later years he gave much of his energy to the study of human population growth; important as this has been it is not, at least to me, so fascinating as the *Drosophila* researches. One feels that he may have been near that elusive sprite, a genuine "law" of mortality.

Pearl was not a particularly eloquent lecturer, but he was a great and inspiring teacher, beloved by those who worked with him and large-minded enough to encourage those working on subjects or along paths which did not attract him. To those who only met him casually he may sometimes have seemed a trifle cynical ("hard-boiled" is, I believe, the idiomatic term). Actually he was one of the kindest of men, and took immense pains to be of service to others. Indeed it is as a humanist that I now think of him. He did fine scientific work, but his personal influence on friends and pupils may well have benefited science more than his direct contributions to it. He broadened the outlook and raised the courage of all who came under his influence. It is very hard for a pure Cockney like me (in a life of more than sixty years I have never passed more than three consecutive months at a greater distance than twelve miles from Shoreditch Church), when he thinks of an American, *not* to picture a thin man with a cigar in the corner of his mouth talking about dollars in a nasal voice and always in a hurry. But in my case this phantasm is at once dispelled by the gracious image of a cultivated gentleman who loved to talk *at leisure*, over a glass of wine, about men, women, and books. That was Raymond Pearl.

WILLIAM WALLACE, M.D., F.R.A.M.

Dr. William Wallace, who recently died at the age of 80, was well known as a composer and writer on musical subjects. He was educated at Fettes College and Glasgow University, where he qualified M.B., C.M. in 1885, proceeding to the M.D. in 1888. After qualification he was house-physician and house-surgeon to the throat department of the Royal Infirmary, Glasgow, and subsequently, for two years, house-surgeon to the Eye Infirmary, Glasgow. In the last war he served as a temporary captain in the R.A.M.C. and was ophthalmologist to the Colchester Military Hospital and Inspector of Ophthalmological Centres in the Eastern Command. Among his medical publications was an article in the *R.A.M.C. Journal* in 1921 on methods of examining the vision of recruits and soldiers. He pursued his second profession—that of music—with unabated interest from the eighteen-nineties till the beginning of the war of 1914–18. His early orchestral work, "The Passing of Beatrice," was first produced at the Crystal Palace in 1893. In a series of orchestral tone-poems one of the most famous was "Villon." Dr. Wallace was the author of several works on musical subjects, and his versatility is shown by the fact that he also contributed articles on Greek typography to the *Journal of Hellenic Studies*. He had, as well, a high degree of skill as a painter, and a hundred of his water-colour drawings of injuries to the eye are preserved in the Army Medical War Museum.

Medical Notes in Parliament

The Nation's Bread in Wartime

Replying to a request by Lord Strabolgi on December 19 in the House of Lords, Lord WOOLTON made a statement regarding bread. He said the bakers had never failed to provide the bombed areas with bread. The Government had arranged to give for three months a subsidy equal to 1d. on the quartern loaf, payable on all bread sold at 8d. per quartern or less. He had arranged with the bakers that they would supply at the same price either a white bread or a wholemeal bread. He had decided on an 85% extraction for wholemeal flour. This wholemeal would be supplied at the same price as "national straight run" white flour and would contain the necessary quantities of vitamin B. The virtues of wholemeal bread had been known to the public and widely advertised for years, but the quantity of bread made from high-extraction flour was only a little over 8% of the bread consumption of the country. Most people did not like to change habits or did not like the bread. He could not insist on the public eating wholemeal bread, but drew public attention to the advantages which those who ate it were likely to obtain. Public interest had been roused about the fortifying of white bread. For some four years before the war the flour-milling industry of this country had spent money on research for the best means of remedying the recognized deficiency of white flour in vitamin B_1. They found a means of introducing it into white flour without affecting the appearance, the baking, or the keeping. The Government considered a report on this matter by its Scientific Subcommittee. It asked him to secure that white flour was fortified with vitamin B, and concurrently that wholemeal bread was available to all the public who wanted it. Supplies of vitamin B, would not be available in any quantity until the spring of 1941—probably in May. The committee also drew attention to the importance of the addition of certain calcium salts to flour. The printed literature of the Ministry of Food would continue to advocate the virtues of wholemeal bread for those who found it a suitable diet.

Lord BALFOUR OF BURLEIGH said that from the earliest days of the war the Medical Research Council gave the question of bread attention. It decided to recommend that bread should be made of an extraction of the wheat grain of not less than 80% to 85% in order to contain the germ, as much as possible, of the aleurone layer, and the finer portions of the bran. A further recommendation was that a small percentage of calcium salt should be added to this flour to overcome the defect of bread, especially of bread made from a high-extraction flour, of preventing the utilization of calcium by the body. The addition of calcium would increase calcium retention, to allow better bone and tooth formation. The Medical Research Council found that calcium deficiency had long been a defect of nutrition among people in this country. This deficiency had especially to be overcome in the poorer sections of the community which had difficulty in obtaining the protective foods, milk, cheese, and vegetables. The Medical Research Council thought everybody ought to eat wholemeal bread, but recognized the difficulties Lord Woolton had pointed out. There was immense popular prejudice. The Council would cordially approve the addition of vitamin B to the 70% extraction flour. This would make that flour better, but the Council did not think that even with the addition of calcium and vitamin B it would be as good as the 85% extraction flour. The latter would not make brown bread, but bread of an "off-white" colour.

Lord WOOLTON added that the high-extraction flour would be available to housewives. He would continue to rely on the scientists who had given the results of their research on this problem. It might become necessary to press hard for the consumption of high-extraction flour to save shipping.

Fortified White Flour

In reply to Mr. De La Bère on December 18, Major LLOYD GEORGE said an advisory committee including scientists and representatives of the various trade and other interests involved had been appointed for consultation on administrative and technical questions in connexion with the introduction of synthetic vitamin B and calcium into white flour. The committee had held two meetings and made recommendations on matters of principle and detail. At the same time negotiations had been proceeding with manufacturers and potential manufacturers of aneurin. It was expected that the distribution of fortified flour on a national scale would commence next spring. No monopoly would be given to a particular firm.

Surgery Hours and the Black-out

On December 19 Captain PEVERGOT asserted that panel doctors had in many cases made no attempt to adjust their consulting hours to black-out conditions and that in consequence very few insured persons attended evening surgeries. Mr. MACDONALD answered that at the outbreak of war his Department recommended insurance committees to review the arrangement of surgery hours, having regard to the restriction of lighting and other war conditions. He had no reason to think there was any general dissatisfaction as to surgery hours, but he would inquire into any complaint which might be brought to his notice.

Sir ROBERT YOUNG suggested on the same date that the early closing of chemists' shops made it difficult for persons working to 5.30 or 6 p.m., who had to visit a doctor, to get the medicine prescriptions made up before the shops closed. Mr. HERBERT MORRISON replied that the general closing hours of shops did not apply to the sale of medicine, and so did not prevent chemists from making up doctors' prescriptions at any hour in the evening. Chemists who dispensed national health insurance prescriptions were obliged to be available for service until the hours fixed by the local insurance committee, who had regard for the needs of workers in the locality. He had received no evidence of hardship resulting from chemists closing earlier on account of the black-out and air raids.

Mobile First-aid Units

Replying to Mr. Brooke in the House of Commons on December 19, Mr. MACDONALD stated that the average number of occasions on which a mobile first-aid unit had been sent to an incident in London during October and November was 4.4. In addition the doctor, usually accompanied by a nurse, had been sent out without the rest of the unit on 5.3 occasions on the average, making a total of approximately 10. Up to the present these units had been used rather less than was expected, but their use, which had proved of great value, must depend upon the nature of the incidents. The nursing personnel were available to help in the work of the hospital or first-aid post on which the unit was based, and to reinforce neighbouring first-aid posts when necessary.

Immunized Persons as Disease Carriers

Asked by Mr. Groves if he had considered the danger of persons immunized against diphtheria and enteric fever becoming carriers of the germs of these diseases, Mr. MACDONALD replied on December 19 that when a majority of the child population had been immunized against diphtheria the danger which Mr. Groves apprehended would for all practical purposes disappear. There was no evidence that a community a portion of which had been immunized against enteric fever contained a greater proportion of carriers than one not so immunized.

Replying on the same date to Major Heilgers, Mr. MACDONALD said the immunization of children against diphtheria in the large numbers which he desired could be most expeditiously achieved by means of sessions at selected places, where children could be assembled in convenient numbers. The free supply of material to local authorities was in a form convenient for this, and not for distribution to private medical practitioners. Major HEILGERS further reported that there appeared to be a shortage of diphtheria toxoid at the Ipswich Emergency Laboratory. Mr. MACDONALD said all demands which had been made on this laboratory would be met within the next few days. The stocks at present held by the laboratories were generally sufficient to meet current requirements, and provision had been made for further substantial supplies as required.

Medical News

Air Vice-Marshal H. E. Whittingham, C.B.E., has been appointed Director-General, R.A.F. Medical Services, Air Ministry, from March 1, in succession to Air Marshal Sir Victor Richardson, K.B.E., C.B.

Dr. Robert D. Defries has been appointed Director of the School of Hygiene and of the Connaught Laboratories, University of Toronto. During the past twenty-five years he has been prominent in the work of these two institutes, having early in 1915 become actively associated with the late Dr. J. G. FitzGerald, whom he now succeeds.

A meeting of the Society for the Study of Inebriety will be held at the Medical Society of London, 11, Chandos Street, W., on Tuesday, January 14, at 4 p.m., when Dr. George B. Wilson will present a paper on "A Seventy-five Years' Survey of the Liquor Problem in Great Britain."

The B.B.C. announces that from January 6 to 10 a series of special health talks for schools will be given each morning at 11 a.m. on how germs spread; the body's defences; cleanliness and health; cool heads and warm feet; sleep and rest.

A meeting of the Shaftesbury Military Hospital Medical Society will be held at the hospital on Tuesday, January 7, when clinical cases presented by members will be on view from 2.30 p.m. to 3 p.m. A discussion will follow.

Canada, states the *Daily Telegraph*, is to set up a blood "bank" to provide transfusions for 20,000 military and civilian casualties. The Canadian Government will provide all equipment and meet the running costs of the scheme.

According to a report in the *Times* the American Red Cross is sending to this country sufficient material to immunize 1,000,000 children against diphtheria. In response to an appeal from the Ministry of Health one-fifth of this—that is, material for immunizing 200,000 children—is arriving by air; the remainder is following by sea. It is stated that the Ministry of Health aims at immunizing at least 5,000,000 children before the beginning of the diphtheria season. There are in this country some 11,500,000 children under 15 years of age.

The New Year Honours List includes the award of the O.B.E. (Civil) to Mr. Edward Thomas Both of Adelaide, South Australia, the designer of the artificial respirator which was adopted by Lord Nuffield for distribution among the hospitals of the Empire.

Dr. H. Douglas Singer of Chicago has been elected president of the American Neurological Association.

Universities and Colleges

UNIVERSITY OF CAMBRIDGE

The following candidates have been approved at the examination indicated:

FINAL M.B.—*Part II (Principles and Practice of Physic, Pathology and Pharmacology)*: W. W. Brigden, W. R. Burkitt, O. Clarke, R. E. W. B. Comerford, J. G. Craddock, G. E. H. Enderby, M. A. Fawkes, J. S. Hesketh, A. Holmes-Smith, D. J. Howell, D. M. Jackson, F. S. Jackson, D. W. M. James, E. J. C. Kendall, D. Laing, L. A. Little, I. B. Mackay, W. B. D. Maile, A. Maples, P. F. Milling, R. Morton, A. G. E. Pearse, F. T. G. Prunty, L. Read, T. W. Rowntree, W. M. Scott, C. S. N. Swan, D. E. Thompson, R. C. Tufton, D. N. White, F. A. Whitlock, J. O. D. Williams, F. J. Y. Wood. *Women:* M. Redfern Davies, R. M. Stevenson.

UNIVERSITY OF BRISTOL

The following candidates have been approved at the examinations indicated:

FINAL M.B., CH.B.—N. F. W. Brueton, Gwendolen M. Higgins, Megan E. Jones, J. M. Joshua, J. K. Lewis, T. E. Lloyd, H. Mullen, P. W. J. Searle, R. D. R. Shanks. *In Group I (completing examination)*: G. H. Harvey, J. W. J. Newton, D. A. Squire. *In Group II (completing examination)*: Winifred M. Curgenven-Robertson, Clara J. Fraser, Ruth M. Hunter.

ROYAL COLLEGE OF SURGEONS OF EDINBURGH

At a meeting of the Royal College of Surgeons of Edinburgh, held on December 17, with Dr. H. M. Traquair, President, in the chair, the following candidates, having passed the requisite examinations, were admitted Fellows:

L. H. Aitken, A. S. Dill-Russell, C. J. H. Gibson, C. Latto, C. T. Moller, Elizabeth McCallum, G. D. McDowall, I. A. M. MacLeod, M. S. Nirankari, H. Wapshaw.

The Services

ARMY AWARDS

Military Cross

The M.C. has been awarded to Major Walter Dalgleish Jackson and Lieuts. Ronald Rodger Gordon and Martin Turner Read, R.A.M.C., in recognition of gallantry in France and Flanders; and to Lieut. John Graham Lord, R.A.M.C., in recognition of gallant conduct in action with the enemy.

Mentions in Dispatches

The names of the following have been brought to notice in recognition of distinguished services in connexion with operations in the field, March to June, 1940.

Commands and Staff: Major-General J. W. L. Scott, D.S.O.; Colonels R. Errington, C.B.E., M.C., T.D., C. L. Franklin, M.C., A. Hood, C.B.E., E. M. O'Neill, D.S.O., A. C. Searle, M.C., and S. G. Walker; Lieut.-Colonel (Acting Colonel) J. C. A. Dowse.

Royal Army Medical Corps: Lieut.-Colonels S. Arnott, D.S.O., J. W. Hyatt, A. R. Barlas, J. H. Ward, D.S.O., M.C., C. H. K. Smith, M.C., D. McVicker, M.C., F. G. Flood, M.C., A. Bremner, G. G. Drummond, W. A. Ramsay, T. Parr, R. E. Rees, M.C., K. A. M. Tomoroy, and W. H. Marston; Majors (Acting Lieut.-Colonels) L. C. Lade, J. H. Bayley, M.C., and E. P. N. Creagh; Captains (Acting Lieut.-Colonels) C. R. Sadler and H. L. G. Hughes, D.S.O., M.C.; Major (Temporary Lieut.-Colonel) W. M. Cameron, O.B.E.; Majors J. G. Black, J. A. Brocklebank, R. G. Evans, F. A. Donolly, W. E. Underwood, J. Houston, J. Boyle, G. Punshon, A. R. H. Champion, A. E. King, L. B. Stott, J. D. W. McCracken, H. F. Wattsford, Y. Moore, O. D. Jarvis, O.B.E., D. A. O. Wilson, E. I. B. Harvey, A. D. Bourne, G. R. McNab, R. T. P. Tweedy, W. B. F. Orr (since deceased), A. D. Davidson, S. A. Maddocks, J. E. Morrison, St. C. E. J. Barrett, A. D. Briscoe, F. B. Mackenzie, D.S.O., M.C., and D. N. Nicholson; Captains (Acting Majors) J. H. J. Crosse and A. G. Whitfield; Lieuts. (Acting Majors) A. C. Stevenson and D. P. McCoy; Lieut. (Temporary Major) D. M. Jones; Captains F. Murray, W. G. Bateson, I. B. Pirie, O. M. Walker, W. H. Valentine, W. O'Callaghan, R. Rutherford, F. V. Allen, P. E. Cresswell, L. Evans, and F. J. Henderson-Begg; Lieuts. (Acting Captains) H. W. Beetham and J. A. Farrell; Lieuts. R. C. Little, D. I. McCallum, A. S. C. Hobson, J. W. Landells, J. W. Dowzer, P. K. Walker, R. Bevan, C. E. Stuart, J. P. Lane, J. G. Munro, F. R. Store, J. C. Taylor, P. Louis, K. D. Moynagh, D. H. Jones, C. Hope, W. H. Hylton, M. R. Grace, C. D. Preston, F. J. D. Webster, C. D. Anderson, J. A. Farfor, M. R. Joseph, G. H. Scoular, E. Cullen, A. T. Blair, R. MacKay, M. W. Paterson, G. S. Sheill, W. G. J. Gordon, J. H. Rose, N. C. Rodgers, J. J. Hogan, M. Herman, and L. H. Crosskey.

The names of the following have been brought to notice in recognition of distinguished services in connexion with operations in Norway.

Commands and Staff: Colonels G. A. Blake and P. H. Mitchiner, C.B.E., T.D.; Lieut.-Colonel (Acting Colonel) W. E. Tyndall, M.C.; Major (Acting Lieut.-Colonel) A. J. Beveridge, O.B.E., M.C.; Captain (Acting Major) R. O. Brooks.

Royal Army Medical Corps: Captain (Temporary Major) J. Bruce; Lieuts. A. E. Loden and A. E. Burgess.

CASUALTIES IN THE MEDICAL SERVICES

ROYAL NAVY

Past and present members of the Liverpool Medical School will learn with regret that Probationary Surgeon-Lieutenant BEN HAROLD BRINDLE, R.N.V.R., was among those who lost their lives when H.M.S. *Forfar* was sunk by enemy action. He joined the R.N.V.R. only a few weeks ago, after returning from a voyage to Australia as ship surgeon. After graduating M.B., Ch.B at Liverpool in June, 1938, he was resident for a time at the David Lewis Northern Hospital and at Walton

Hospital, Liverpool. The sympathy of the profession and especially of those members, many of whom are in the Services, who belonged to his year at Liverpool, will go out to his mother, his fiancée, and to his brother, Major W. S Brindle, R.A.M.C., in their tragic loss.

ROYAL ARMY MEDICAL CORPS

Wounded

Lieut. Robert Elmer Horton

EPIDEMIOLOGICAL NOTES

Infectious Diseases for the Week

Increases were recorded in England and Wales during the week in the incidence of diphtheria, measles, and whooping-cough, and of cerebrospinal fever, enteric fever, and dysentery. All these diseases, and also scarlet fever, pneumonia, and acute poliomyelitis, are more prevalent now than they were during the corresponding week last year; in some instances the increase is only slight. The incidence of most of these diseases has been rising steadily in the last few weeks, and this might cause disquiet were it not for the fact that cases of diphtheria and scarlet fever are fewer in number than they were in the last "normal" year—namely, 1938. Comparable figures for measles and whooping-cough are not available.

Although the position as regards incidence for the country as a whole is still favourable, new factors have raised new problems which the usual measures of disinfection and isolation fail to meet. The evacuation of large numbers of susceptible subjects to areas hitherto more or less immune from infectious diseases in other than sporadic form increases the risks of spread, but if to this are added overcrowding in billets and inadequate hospital accommodation for suspected or manifest cases, then sooner or later the resources of the reception areas will be overtaxed. Although there have been no serious outbreaks of enteric fever so far, the risk of pollution of water supplies by air-raid damage to the drainage system has led to increasing inoculation against this disease. Little attention has been paid to whooping-cough, although protective measures are available, because so far the incidence has been comparatively low and the attack generally benign.

As regards measles, no reliable method of active immunization has yet been devised, and the physician must therefore wait until there has been exposure to the disease (unless deliberate exposure is practised) before the modifying effect of immune measles serum can be conferred. For this purpose serum from adults, such as that which is being collected from donors for the E.M.S. blood or serum "banks," could, if necessary, be made available in reception areas as the need arises. For temporary protection of selected individuals in whom an attack of any kind might be detrimental convalescent serum is the only consistently reliable agent, although some preparations of placental extracts have yielded good results.

The incidence of diphtheria in the week under review is highest in: Lancaster 275 (Liverpool 94, Manchester 24, Salford 18, Bolton 13, Bootle 12, Wigan 10, Widnes M.B. 10); Glamorgan 147 (Swansea 64, Cardiff 10, Aberdare U.D. 10, Mountain Ash U.D. 8, Llantrisant and Llantwitfardre R.D. 8, and from 1 to 7 in 16 out of the remaining 19 urban and rural districts); Yorks, West Riding, 132 (Sheffield 29, Bradford 15, Leeds 8, and widely scattered in smaller administrative areas); Devon 70 (Plymouth 37, Exeter 15); Chester 65; Durham 61 (Sunderland 11, Jarrow 11, South Shields 8); Gloucester 56 (Bristol 24, Gloucester 21); Warwick 56 (Birmingham 43); London 53 (ranging from 1 to 6 in 20 out of the 29 metropolitan boroughs). The disease is at present more deadly than it was in 1938, when incidence was higher; many factors, some extrinsic, may be responsible, but increased frequency of the more virulent starch-fermenting strains is probably the most important single factor. In Scotland notifications fell slightly from the level of the previous week, but remain greatly in excess of those recorded in the corresponding weeks of 1939 and 1938; no fewer than forty-three out of the fifty-five administrative areas were affected, notably the counties of Lanark 35, Fife 21, Dumfries 16, Renfrew 14, Clackmannan 10, and the burghs of Glasgow 139, Dundee 48, Edinburgh 34, Paisley 21, Aberdeen 19, Kirkcaldy 10. In Scotland, too, the prevailing type, as reflected in deaths, is highly virulent.

No. 45

INFECTIOUS DISEASES AND VITAL STATISTICS

We print below a summary of Infectious Diseases and Vital Statistics in the British Isles during the week ended November 30, 1940.

Figures of Principal Notifiable Diseases for the week and those for the corresponding week last year, for: (a) England and Wales (London included) (b) London (administrative county) (c) Scotland (d) Eire, (e) Northern Ireland.

Figures of Births and Deaths, and of Deaths recorded under each infectious disease, are for: (a) The 126 great towns in England and Wales (including London) (b) London (administrative county) (c) The 16 principal towns in Scotland (d) The 13 principal towns in Eire (e) The 10 principal towns in Northern Ireland.

A dash — denotes no cases; a blank space denotes disease not notifiable or no return available.

Disease	1940					1939 (Corresponding Week)

TELEGRAPHIC ADDRESSES.—EDITOR, *Aitiology Westcent, London;* SECRETARY, *Mediocra Westcent, London.*

B.M.A. SCOTTISH OFFICE: 7, Drumsheugh Gardens, Edinburgh.

QUERIES AND ANSWERS

Blood-stained Semen

"J. M." writes: With reference to the notes on blood-stained semen, while in Port Elizabeth, South Africa, in 1910 I was called out to see a Kaffir who complained that he had something wrong with his penis. The hut was very dark, but a candle was found and I saw a pool of blood on the floor which would have filled a small teacup. I got him to pass water, but this was quite clear, showing that the bladder and kidneys were sound. He passed a blood cast of the urethra about four to five inches long, showing that the blood came from the urethra and was due to either chronic gonorrhoea or the congestion following too frequent coitus. Kaffirs are well known for their proneness to overmuch sexual intercourse.

Income Tax

E.M.S.—Travelling Allowance

"M.D." asks if the travelling allowance received as a part-time consultant to the E.M.S. is taxable.

*** In strictness the allowance should be excluded from the taxable receipts, and any expenses incurred in doing the work should be excluded from the professional expenses. If the latter amount is difficult to calculate (as may very well be the case where a car is used) it may be more convenient to treat the amount of allowance received as taxable and claim the whole of the appropriate travelling expenses.

Partner on Military Service—Earned Income

"T. R. S." is one of five partners. He was called up for military service in September, 1939, and his pay and family allowance are paid into the partnership pool. A locum is employed, living in "T. R. S.'s" house, the general expense of which is borne by "T. R. S." The inspector of taxes states that no "earned income relief" is due in respect of his share of the practice profits.

*** We do not think that the inspector's attitude would be supported by the authorities. Apart from the hardship which the view he takes of the position would inflict on partners on military service, "T. R. S." is presumably available for consultation from time to time on matters of importance affecting the conduct of the practice, and from that point of view may still be regarded as something more than a sleeping partner. We advise our correspondent to write to the Secretary, Board of Inland Revenue, Somerset House, W.C.2, explaining the facts and asking that the inspector of taxes may be authorized to withdraw his objection.

LETTERS, NOTES, ETC.

Closed-plaster Treatment of Wounds

"MEDICO from the Jungle" writes: The many articles written on this subject of late make one used to practising among natives smile. Surely the closed-plaster treatment is as old as the trees in the jungle. The only difference between this treatment and jungle treatment is that plaster-of-Paris is used and that greater care is taken in producing good alignment and, therefore, better functional results. In the jungle natives have used bamboo splints encased in mud or cow-dung and leaves for the closed treatment of wounds and fractures since at least 2000 B.C. Even many animals, especially the elephant, treat their own wounds in this way, or at least in a modified form, using mud and leaf-sealed dressing. Many so-called ignorant jungle medicine men were even able to produce good functional results by pulleys made from bamboo and other strips of natural fresh sapling trees. Dr. Winnett Orr certainly was a modern advocate of this treatment, but I myself saw this treatment in a modified form used in White Russian army hospitals in 1919 during the revolution. In the wards of Profs. Petroff and Alexanski for fractures and wounds one came across numerous patients in plaster; they used a modified Winnett Orr's method, leaving a window for drainage of pus, but dressings were applied at very long intervals. All their compound fractures were treated in this way.

Herpes Zoster

Dr. A. H. BARTLEY (Maltby) writes: I have been treating several cases of herpes zoster with such remarkable results that I feel this treatment will be welcomed, having met such persistent cases in the past. Briefly the treatment is this. The eruptions are painted with collodion twice daily for three days; a firm film covers the vesicles, and falls off when these dry up. I give pill cannabis indica 1/4 grain t.i.d. for a week. During this medication the pain gradually diminishes, and is much appreciated by the patient, as most analgesics, except morphine, have little effect. The most gratifying part is the good sleep at night, which is the most distressing part of the disease usually. Most of my cases have been in men who were unable to give up their work and were able to carry on with this treatment.

Hospital Infection of Wounds

Dr. BERNARD ROWLANDS writes: I wish to deal with only one source of infection in hospital. It may be possible to combat the menace of dust-borne infection in the wards by modifying their arrangement or construction. As a number of our hospitals will have to be rebuilt before long the subject of improved construction and arrangement is well worth careful thought now. I suggest the transfer of patients from one section of a suitably constructed ward to another section during sweeping and bed-making. A dustproof drop-curtain would then operate to cut off the area in which the patients would then be lying. In some hospitals it would be possible to wheel the vacated beds to a special room for the purpose of re-making them. I hope that when the rebuilding of our hospitals is taken in hand our surgeons will put forward any ideas they may have formed on this subject.

The Mother's Share in Family Allowances

THE CHAIRMAN of the Six Point Group (Miss Dorothy Evans) writes: No doubt many of your readers have studied with interest the pamphlet, *An Aylesbury Broadside*, issued by the *Lancet*, putting forward a proposal for family allowances. My committee hails with approval a scheme from such an influential quarter to remedy a situation which we have long deplored—namely, that the nation's mothers have to carry out in the majority of homes their task of citizen-building without the necessary materials. Moreover, they are called upon to do a great variety of jobs—cooking, catering, cleaning, sick nursing, sewing, infant education, household decoration and repairs of many kinds—and all these without any cash remuneration whatever, as the pamphlet rightly points out. The scheme put forward, while providing for an allowance from the State to the mother in respect of each child if the family income falls below subsistence level, does not tackle the question of the mother's own nutriment, or provide for any small allowance of spending money for her very own, apart from sums which she administers for others. A diagram is given illustrating the proportions spent on various items in a sample budget. There is an item—the husband's pocket money—illustrated by a drawing of a man enjoying a smoke. There is no item the wife's pocket money—nor is she depicted in the act of indulging in any personal gratification. I write in the hope that a scheme of family allowances sponsored by the medical profession will include not only an allowance to the mother wherewith she can feed and clothe her child if the family income is not adequate, but an allowance to the mother or guardian whose time is spent on the tasks necessary for the adequate nurture of the child. The scheme will not achieve the physical improvement hoped for unless this is done. The mother during the nursing stage must have increased nourishment beyond the needs of an ordinary adult. If this is denied and she goes short, as the reports on malnutrition all show that she does, during the arduous years of her childbearing, her offspring will inevitably be under par.

Chocolate in Wartime

Messrs. Cadbury of Bournville send us at the end of each year samples of their products, and, although some of the raw materials used in the manufacture of chocolate are now rationed and Government contracts have to be met, the pleasant custom was continued in 1940, and the usual standard of quality maintained.

SUPPLEMENT TO THE
BRITISH MEDICAL JOURNAL
LONDON SATURDAY JANUARY 4 1940

MEDICAL PLANNING COMMISSION

THE FUTURE OF THE BRITISH MEDICAL SERVICES

The British Medical Association has, after much consideration, set up a Medical Planning Commission and has invited—and welcomes—the co-operation of the English Royal Colleges and the Scottish Corporations in this work. The terms of reference are as follows:

> "To study wartime developments and their effects on the country's medical services both present and future."

In deciding the size and in choosing the personnel of the Commission the Association has had the view that such a body will be in the nature of an assembly, meeting from time to time to debate large questions of principle. The detailed work of the Commission will be undertaken in committees and subcommittees of the usual size, and their resolutions and recommendations will come for discussion before the Commission itself.

The Association believes that any disadvantage which may be attached to the size of the Commission will be more than offset by the advantage of its fully representative character. Much thought has been given to the age distribution of members of the Commission as well as to its representative character. Its constitution is as follows:

President: T. Fraser, C.B.E., D.S.O., M.B., Ch.B., Aberdeen. Consulting Physician, Aberdeen Royal Infirmary.

Chairman of Council: H. S. Souttar, C.B.E., D.M., M.Ch., F.R.C.S., F.R.A.C.S., Surgeon, London Hospital.

Chairman of Representative Body: H. Guy Dain, LL.D., M.B., Direct Representative of Medical Profession on General Medical Council: late Chairman of Insurance Acts Committee.

Treasurer: J. W. Bone, M.B., C.M., Direct Representative of Medical Profession on General Medical Council: Chairman of General Practice Committee: late Chairman of Medico-Political Committee.

Deputy Chairman of Representative Body: Peter Macdonald, M.D., Ophthalmic and Aural Surgeon, York County Hospital: Chairman of B.M.A. Hospitals Committee.

Royal College of Physicians: 4 nominees, to be announced later.

Royal College of Surgeons: Sir James Walton, K.C.V.O., M.S., F.R.C.S., London; Sir Alfred Webb-Johnson, C.B.E., D.S.O., F.R.C.S., London. Two further nominees, to be announced later.

Royal College of Obstetricians and Gynaecologists: 3 nominees, to be announced later.

Royal College of Physicians, Edinburgh: Charles McNeil, M.D., F.R.C.P., Edinburgh.

Royal College of Surgeons, Edinburgh: Henry Wade, C.M.G., D.S.O., F.R.C.S.Ed., F.R.A.C.S., Edinburgh.

Royal Faculty of Physicians and Surgeons of Glasgow: John Henderson, M.D., F.R.F.P.S., Glasgow.

Society of Medical Officers of Health: G. F. Buchan, M.D., F.R.C.P., Willesden; A. Massey, M.D., Coventry: a County Medical Officer of Health.

Faculty of Radiologists: One nominee, to be announced later.

Medical Women's Federation: Mona Macnaughton, M.B., Ch.B., Newcastle-upon-Tyne; Doris M. Odlum, M.R.C.S., L.R.C.P., D.P.H., London.

Parliamentary Medical Committee: Sir Francis Fremantle, O.B.E., M.P., D.M., F.R.C.P., F.R.C.S.; Haden Guest, M.C., M.P., M.R.C.S., L.R.C.P.

Allen, Frederick Martine Brice, M.D., F.R.C.P., Belfast. Hon. Physician, Belfast Hospital for Children: Member of Council of B.M.A.; Hon. Secretary, Northern Ireland Branch of B.M.A.

Ball, Sir William Girling, F.R.C.S., London. Surgeon, St. Bartholomew's Hospital; Dean of St. Bartholomew's Hospital Medical School; Dean of Faculty of Medicine, University of London.

Bolam, R. Mason, M.B., Ch.B., Newcastle-upon-Tyne. Hon. Assistant, Skin Department, Royal Victoria Infirmary, Newcastle-upon-Tyne; Hon. Secretary, North of England Branch of B.M.A.

Boyde, H. C., M.R.C.S., L.R.C.P., London. Hon. Secretary, Stratford Division, B.M.A.

Brown, James Alexander, M.D., Birmingham. Member of Insurance Acts Committee; Chairman of Birmingham Panel Committee.

Cameron, James Inglis, M.B., Ch.B., F.R.F.P.S., Glasgow. Hon. Secretary, Glasgow Division, B.M.A.

Carter, O. C., M.B., B.S., Bournemouth. Hon. Secretary, Bournemouth Division, B.M.A.; Member of Journal Committee.

Cope, V. Zachary, M.S., F.R.C.S., London. Surgeon, St. Mary's Hospital; Senior Surgeon, Bolingbroke Hospital; President, Medical Society of London; Member of Council of B.M.A.

Coyle, Cecil Dermot, M.B., B.Ch., London. Medical Superintendent of Fulham Hospital.

Daley, William Allen, M.D., F.R.C.P., D.P.H., London. Chief Medical Officer, London County Council.

Dawson of Penn, Viscount, P.C., G.C.V.O., K.C.B., M.D., F.R.C.P., LL.D., F.R.C.S.(Hon.), London. Extra Physician, London Hospital; Past President of Royal College of Physicians and Past President of B.M.A.

Dickson, J. W. L., M.B., Ch.B., Middlesbrough. Secretary, *Middlesbrough Panel Committee.*

Dilling, Walter James, M.B., Ch.B., Liverpool. Dean of Faculty of Medicine, University of Liverpool; Professor of Pharmacology and General Therapeutics, University of Liverpool.

Dyke, Sidney Campbell, D.M., F.R.C.P., Tettenhall, Staffs. Consulting Pathologist, Royal Hospital, Wolverhampton; President, Association of Clinical Pathologists.

Evans, Geoffrey, M.D., F.R.C.P., London. *Physician, St.* Bartholomew's Hospital.

Gordon, Ronald Grey, M.D., F.R.C.P., Limpley Stoke, near Bath. Physician, Royal United Hospital and Children's Orthopaedic Hospital, Bath: late Deputy Chairman of Representative Body of B.M.A.; Member of Council of B.M.A.; Chairman of Journal Committee and Board of Directors of *British Medical Journal.*

Greenfield, D. G., M.D., F.R.C.S., Rushden. Chairman of Conference of Local Medical and Panel Committees; Member of Insurance Acts Committee and of its Rural Practitioners Subcommittee.

Gregg, Edward Andrew, L.R.C.P. & S., London. Member of Council of B.M.A.; Chairman of Insurance Acts Committee of B.M.A.; Chairman of London Panel Committee; and Past-Chairman of London Insurance Committee.

Gray, Frank, M.B., London. Chairman of London Public Medical Service; Member of Council of B.M.A.; Member of Insurance Acts and General Practice Committees.

Harman, N. Bishop, LL.D., F.R.C.S., London. Chairman, Ophthalmic Group Committee; Member of Council of B.M.A.; late Treasurer of B.M.A.

Hastings, Somerville, M.S., F.R.C.S., London, Surgeon-in-Charge of Ear, Nose, and Throat Department and Lecturer, Middlesex Hospital; late Member of Parliament for Reading; Member of London County Council and Chairman of London County Council Hospitals and Medical Services Committee.

Jones, John Arthur Llewelyn Vaughan, M.B., Ch.B., Leeds, Hon. Secretary, Leeds Public Medical Service; Member of General Practice Committee; Hon. Secretary, Leeds Division.

Mackintosh, J. M., M.D., D.P.H., Edinburgh, late Chief Medical Officer, Department of Health for Scotland.

MacWilliam, Henry Herbert M.B., B.Ch., D.P.H., Liverpool, Medical Superintendent, Walton Hospital, Liverpool.

Marks, Urban, M.R.C.S., L.R.C.P., Swansea, Member of the Public Medical Services Subcommittee and of Swansea Panel Committee; late Chairman of Swansea Panel Committee; Assistant Physician to the Swansea Hospital.

Martin, Charles Gutherless, M.R.C.S., L.R.C.P., London, Hon. Secretary, Metropolitan Counties Branch of B.M.A.

Millar, A. F. Wilkie, M.D., Edinburgh, Hon. Secretary and Chairman, Edinburgh and Leith Division, B.M.A.; Member of Scottish Committee and Insurance Acts Committee.

Miller, James Blakely, M.D., D.P.H., Bishopbriggs, Lanarkshire, Chairman, Scottish Colliery Surgeons Committee; late Chairman of B.M.A. Scottish Committee and Scottish Health Services Committee; Member of Council of B.M.A.

Murray, David Stark, M.B., Ch.B., Richmond, Surrey, Hon. Pathologist, Royal Hospital, Richmond, Victoria Hospital, Kingston, and Teddington Memorial Hospital; President of Surrey Branch of B.M.A.; Editor of *Medicine To-day and To-morrow*.

Newell, Robert Leech, M.D., F.R.C.S., Cheadle, Cheshire, Assistant Surgeon, Manchester Royal Infirmary; Lecturer in Surgery, Manchester University; Member of Council of B.M.A.; Member of B.M.A. Hospitals, Health Services Committees.

Picken, Ralph Montgomery Fullarton, M.B., Ch.B., D.P.H., Cardiff, Mansel Talbot Professor of Preventive Medicine, Welsh National School of Medicine; Member of Council of B.M.A.; Chairman of Public Health Committee.

Platt, Harry, M.D., M.S., F.R.C.S., Manchester, Professor of Orthopaedic Surgery, Manchester University; Hon. Orthopaedic Surgeon, Manchester Royal Infirmary.

Shanks, Seymour Cochrane, M.D., M.R.C.P., London, Hon. Director *X*-ray Diagnostic Department, University College Hospital; President, Faculty of Radiologists.

Simpson, Robert Gordon, M.B., B.S., D.T.M., London, Hon. Medical Officer, Wood Green and Southgate Hospital; Chairman, North Middlesex Division of B.M.A.

Smith Sydney Alfred, M.D., F.R.C.P.Ed., F.R.S.Ed., D.P.H., Edinburgh, Regius Professor of Forensic Medicine, Edinburgh University; Dean of Faculty of Medicine, Edinburgh University.

Stewart, Donald, M.D., F.R.C.P.Ed., Birmingham, Hon. Secretary, Association of Industrial Medical Officers; late Medical Officer, Imperial Chemical Industries.

Wand, S., M.B., Ch.B., Birmingham, Member of Council, Insurance Acts Committee, General Practice (late Medico-Political) Committee, Public Medical Services Subcommittee.

Wigfield, Alan Scott, M.B., B.S., Buntingford, Herts, Physician, Royston Cottage Hospital; Hon. Secretary, East Herts Division of B.M.A.

Williams, Oscar, M.B., B.S., Llanelly, S. Wales, Member of Welsh Committee of B.M.A.

Wilson, David, M.B., B.S., Torquay, Honorary Ophthalmic Surgeon, Torbay Hospital; Member of Ophthalmic Group Committee of B.M.A.

Winstanley, S. A., M.B., Ch.B., Urmston, Chairman of Lancashire County Panel Committee and Past Chairman of Lancashire Insurance Committee; Chairman, Manchester Division, B.M.A.; Member, Insurance Acts Committee.

The Commission has power to co-opt additional members, if necessary, to secure representation of a particular class of experience not otherwise represented on the Committee.

The Ministry of Health and the Department of Health for Scotland have been invited to appoint observers.

TREATMENT OF VENEREAL DISEASE BY GENERAL PRACTITIONERS

Another scheme for securing adequate treatment at the present time of cases of venereal disease, and one which is particularly suited to the needs of rural areas, is outlined in the latest circular (No. 2226) from the Ministry of Health to local authorities and approved treatment centres. It provides for the employment by local authorities of suitably qualified medical practitioners who would give treatment at their own surgeries during normal hours of attendance. The procedure, which has been agreed with the British Medical Association, is that local authorities, having decided which areas should be served in this way and the number of doctors required for the work, should invite all practitioners in the area to apply for service, and select from these the number required. Practitioners who apply must provide evidence that they have performed the following operations: (1) spread microscope slides with discharge from twelve patients (including six females) for examination for gonococci; (2) scraped three lesions suspected of being early syphilitic, and collected in twelve capillary tubes the juice thus made to ooze from them; (3) taken six specimens of blood; (4) given twelve intravenous injections of neoarsphenamine or of stabilarsan and twelve intramuscular or deep subcutaneous injections of bismuth compound. Those who desire to qualify for service will be given training facilities at any treatment centre. The fees payable will be as follows:

For each initial attendance for diagnosis and treatment	10s. 6d.
For every subsequent attendance	7s. 6d.
In every case where a visit to the patient's residence proves necessary during treatment ...	7s. 6d.
(with a mileage allowance of 3d. a mile each way for every mile in excess of two)	

All necessary drugs and equipment will be supplied by the local authority free of charge, and practitioners will be required to keep simple records, suggestions for which accompany the circular. Any local authority not already having a specialist V.D. officer on its staff will appoint such an officer, probably on a half-time basis, whose duty it will be to supervise the treatment given and the records kept, and be available for consultation in difficult or complicated cases. A copy of the Ministry's circular has also been sent to medical officers of health and to medical officers of treatment centres.

Correspondence

Medical Calling Up

SIR,—I would like to support Dr. Cecil B. F. Tivy in his letter (*Supplement*, December 14, p. 53) that: (1) Doctors of the R.A.M.C should be kept for medical duties and administrative work handed to laymen. Why, for instance, should one spend years acquiring medical knowledge, enter the Army, and be used to see to washing contracts, inspection of kit, dealing with correspondence about a hundred and one things, of which not even the one has any medical bearing? (2) Reserves need not be kept idle.

My own case will illustrate the point. I entered the Army in September, 1939. Since then I have averaged not more than a quarter of an hour's medical work per day: and that is literally true. Part of the time is understandable, for we were standing by for embarkation, manning posts in prospect of an invasion, etc., but since the acute period has subsided I have been asked by a surgeon to help with his work, as I had had the particular experience he required. Despite all applications for leave while the unit was inactive the request was refused: so I remain doing nothing. Surely it would not be impossible to release doctors temporarily, on the assurance that they would be available at forty-eight hours' notice.—I am, etc.,

Dec. 17 R.A.M.C. OFFICER.

British Medical Association

PROCEEDINGS OF COUNCIL

WEDNESDAY, DECEMBER 11, 1940

A meeting of the Council of the Association was held at B.M.A. House, Tavistock Square, London, on December 11. Mr. H. S. Souttar, Chairman of Council, presided, and there were also present:

Dr. J. W. Bone (Treasurer), Dr. Peter Macdonald (Deputy Chairman of Representative Body), Mr. N. Bishop Harman (Immediate Past Treasurer), Mr. E. R. Bhodes, Prof. A. H. Burgess, Mr. V. Zachary Cope, Mr. W. McAdam Eccles, Dr. F. W. Grant, Dr. E. Gray, Dr. E. A. Gre[illegible], Colonel W. L. Harnett, I.M.S. (ret.), Dr. W. Irvine, M[illegible] Dr. Lolley, Sir Ewen Maclean, Dr. O. Marriott, Dr. J. C. Matthews, Dr. H. B. Morgan, Mr. R. L. Newell, D[illegible] W. Paterson, Prof. R. M. F. Picken, Colonel A. H. Proctor, Dr. H. R. Robinson, Dr. E. A. Roper, Dr. W. I. Thomas, Dr. S. W[illegible] M[illegible] N. E. Waterfield, Dr. W. N. West-Watson.

The Chairman referred with regret to the deaths since the last meeting of several former members of Council and of two sitting members, Dr. J. R. Prytherch and Dr. F. H. Snell. Among the former members who had died was a Past-President of the Association, Dr. F. G. Thomson of Bath.

The Chairman said that the Council would be sorry to hear of the illness of the Editor, who was likely to be absent from his duties for some time. On his suggestion a message of sympathy was sent to him from the Council.

The Council nominated the Association representatives on the Central Medical War Committee, and in order to make the representation of general practice more adequate added the names of Dr. F. Gray of Wandsworth, Dr. J. M. Johnstone of Stoke-upon-Trent, and Dr. F. W. Grant of Newcastle. Certain nominations for the Scottish Medical War Committee were also approved, it being left to the Scottish Committee at a future meeting to nominate further names.

Medical Planning Commission

The Chairman of Council said that he had suggested to the Executive Committee that the time had come for the profession to give serious consideration to the problem of reconstruction and reorganization in the field of medicine in the post-war era, and the committee had thereupon decided to appoint a B.M.A. Medical Planning Commission to study wartime developments and their effects on the country's medical services both present and future. A large and representative body was in process of appointment which would consist ultimately of about seventy individuals. The English Royal Colleges and the Scottish Royal Corporations have been invited to co-operate. The Society of Medical Officers of Health, so long associated with the medico-political work of the Association, will also assist the Commission through its accredited representatives. The detailed work of the Commission would be undertaken in committees and subcommittees, and the Commission itself would meet only perhaps three times a year to debate larger questions of principle. Correspondence had taken place with the Royal Colleges on the subject, and on the previous day the Comitia of the Royal College of Physicians had accepted the invitation to send representatives and to co-operate fully in the work of the Commission and its committees, and it was believed that the Royal College of Surgeons and the Royal College of Obstetricians and Gynaecologists, which had favourably received the invitation, would also send representatives.

The proposals of the Executive Committee were approved.

Medical Supervision at Air-raid Shelters

The Executive Committee reported on the scale of payment which had been agreed with the Ministry of Health for medical supervision and attendance at public air-raid shelters and emergency rest shelters. The Secretary explained that the proposed payment of salary at the rate of £500 a year for the doctor who was required to stay on duty at the shelter during the whole night related to not more than a dozen shelters in the whole of London, each shelter perhaps accommodating 2,000 or 3,000 people; the scale of payment more usually in force of one guinea a night was for a nightly visit to a shelter or group of shelters and for remaining on call at any time during the night hours.

Dr. Wand raised the whole question of the shelter medical service and related problems. He said that correspondence in recent numbers of the *Journal* had suggested that the Association had not taken a strong enough line in regard to many of the problems now coming forward, including shelter provision, bombed civilians, and the needs of refugees. The general practitioner as represented by the Association had never been consulted on matters of which he knew more than any other group in the profession. On the Horder Committee there was no general practitioner, and the findings of that committee with regard to health measures in the shelters were not strictly in accord with the views which many general practitioners held. Had the Executive Committee ever suggested that the Association should play a part in the work of such committees, or had representative general practitioners with experience of these problems ever been approached in order that their views might be elicited and brought to the notice of those in authority? The members of such committees seemed to be generally consultants or medical officers of health or other people who spent most of their time organizing from their desks with very little experience of the actual problem.

Professor Picken said that Dr. Wand apparently thought that the Association ought to have foreseen the position which had arisen with regard to the shelters, but he had not heard Dr. Wand or anyone else predict the situation whereby in this winter of 1940 many thousands of people would make the shelters their dormitories. If the profession had been able to anticipate such a situation it would have been guilty indeed had it not taken the necessary steps. When the thing did happen the Government was placed in an extremely difficult position and had to act as quickly as possible. It appointed the committee under Lord Horder's chairmanship, which, however, included no general practitioner nor any representative of the public health medical services actively working at this problem in the field. So far as the Association was concerned, the *Journal* was its very important instrument, and great prominence to this subject had been given in its pages and very explicit suggestions made. He thought that one of the most important things the Association could do was to publish information through its *Journal*. To try by ordinary committee methods to deal with this emergency problem would be quite futile. With regard to the health of the people in the air-raid shelters, the big problem seemed to him to be air-borne infection.

Dr. Wand replied that the shelter problem was only one of several in which there had been a like neglect. He could not claim to have visualized the present situation, but nearly twelve months ago he had written a letter advocating that there should be some body in the profession which would have the ear of the Government and bring to its attention such points from time to time.

Dr. F. Gray said that the Ministry of Health's circular envisaged a doctor making a nightly round of many shelters and also spoke of frequent and regular visitation by the medical officer of health. He suggested that the doctor making the nightly round could be of the greatest assistance to the medical officer of health in reporting on the health conditions, and it was to be regretted that the circular made no provision for such co-operation. In Wandsworth twenty-four medical men were making a round of shelters and, entirely unofficially, were furnishing a report on the health conditions.

The Chairman closed the discussion by saying that the Association was in constant contact with the Ministry of Health on the many medical problems arising out of war conditions.

Ophthalmic Hospital Clinics

Mr. Bishop Harman reported further on the question of the establishment by the Central London Ophthalmic Hospital of two branch out-patient departments in the London suburbs, a matter which has aroused a great deal of controversy. The council of management of the hospital had previously announced, following representations by the Association, its decision to discontinue these clinics, but it now urged that the altered conditions occasioned by the bombing of London and the difficulty of access of patients from the outskirts to the centre made it desirable to reverse this policy. A meeting of representatives of the hospital and of the Association, under the chairmanship of Sir Arthur MacNalty, formerly principal medical officer to the Ministry of Health, had recently taken place. Mr. Bishop Harman pointed out that in the districts concerned there were three first-class general hospitals with thoroughly good out-patient departments, plenty of practitioners whose names were on the N.O.T.B. list, and a number of ophthalmic surgeons practising. He understood that all but a very small minority of the medical staff of the hospital itself were opposed to the scheme. If it were allowed to proceed as a war concession it would be exceedingly difficult to get rid of it after the war.

Another member of Council considered that the difficulty of patients getting access to the centre had been exaggerated. Most of the central London hospitals were keeping on their out-patient departments.

On the proposition of Mr. Bishop Harman, seconded by Dr. Henry Robinson, the Council unanimously decided to adhere to its previous decision of April 10, declaring that such action by the hospital authority was contrary to the public interest and to medical ethics and presented grave professional risks to the medical staff of such clinics, and urging the hospital to discontinue them.

Co-operation with Government Departments

It was reported that the Association, on behalf of the profession of the country, had offered its services for the free medical attendance in first-aid treatment of battle casualties or injuries sustained by members of the Home Guard whilst on duty. The Army Council had expressed very great appreciation of this offer, "which accords so fully with the spirit in which the Home Guard was conceived." The Chairman said that the Executive Committee had felt it to be reasonable for the profession to attend free of charge those who were injured on duty whilst giving their services freely to their country.

In view of the development and expansion of the factory medical service at the instance of the Minister of Labour, the Association had offered to Mr. Ernest Bevin its warmest co-operation in the consideration of all problems affecting the health of factory workers.

Various Committee Business

Professor Picken, for the Public Health Executive Committee, reported that the committee had viewed with some anxiety the policy suggested in one of the circulars issued by the Ministry of Health to welfare authorities in connexion with the national milk scheme, inasmuch as it would appear to encourage local authorities to undertake to a greater extent than formerly the distribution of dried milk. The committee had made representations to the Ministry urging that the arrangements for the distribution of dried milk under the scheme, which were not subject to medical supervision, should be administered separately from the arrangements for the issue of dried milk at local authority welfare and maternity centres, which are subject to medical supervision.

Dr. E. A. Gregg, chairman of the Insurance Acts Executive Committee, reported that for a considerable time the question of rising costs in relation to the insurance capitation fee had been under consideration and experts' reports on changes in the cost of living, motoring, and practice expenses had been obtained from time to time. His committee had decided that there was justification for an application for a wartime increase in the capitation fee on the grounds of increased practice expenses and cost of living, and it proposed now to make such an application. The committee had also decided to apply for an increase in the mileage grant on account of the substantial rise in motoring costs.

The Treasurer (Dr. Bone) reported that the financial position of the Association was good, but he reminded the Council of the serious liabilities involved in the building scheme. He was able to announce, however, that a large part of the new northern extension had been rented at scheduled rates. The southern block, which was not completed, had been secured against the weather and made as safe as possible. It was mentioned that in one of the raids on London the presence of mind of the caretaker, Mr. Woodcock, saved the Great Hall probably from destruction when it was hit by an incendiary bomb. Dr. Matthews, for the Organization Committee, stated that 92 medical men were prisoners of war in Germany, 60 of whom were members of the Association. It was proposed to waive their subscriptions during their period of captivity and also if possible to send them copies of the *Journal*.

The meeting of the Council occupied two hours.

Assurance for Doctors

The War Damage Bill, which has been presented to Parliament, provides for compulsory insurance of buildings through the revenue authorities, and voluntary insurance of goods and chattels through Lloyds' underwriters and the insurance companies. The Bill is long and complicated, and it is likely that there will be amendments. The Medical Insurance Agency is closely watching the situation and hopes to make an announcement in the *Supplement* on the subject as soon as full information is available.

WEEKLY POSTGRADUATE DIARY

DIARY OF SOCIETIES AND LECTURES

ROYAL SOCIETY OF MEDICINE

Section of History of Medicine.—Wed., 2.30 p.m. Papers by Sir Walter Langdon-Brown: David Hartley; Dr J. F. Halls Dally: The Life and Times of Jean Nicolas Convisart (1755-1821).

Section of Surgery.—Wed., 2.30 p.m. Paper by Prof. S. Zuckerman: The Problems of Blast Injuries.

VACANCIES

EXAMINING FACTORY SURGEONS.—The following vacant appointments are announced: Brixham (Devonshire); Berkhamsted (Hertfordshire); Liverpool, Garston (Lancashire). Applications to the Chief Inspector of Factories, Cleland House, Page Street, S.W.1, by January 7.

MEDICAL REFEREE UNDER THE WORKMEN'S COMPENSATION ACT, 1925, FOR DERMATOLOGICAL CASES arising in the County Court Districts of Doncaster, East Retford, Mansfield, Newark, Nottingham and Worksop (Circuit No. 18), and Alfreton, Buxton and New Mills, Chesterfield, Ashbourne, Bakewell, Burton-on-Trent, Derby and Long Eaton, Ilkeston, Matlock and Wirksworth (Circuit No. 19). Applications to the Under Secretary of State (Industrial Division), Home Office, Cleland House, Page Street, S.W.1, by January 11.

APPOINTMENTS

MEACHIM, G. L., M.B., Ch.B., Examining Factory Surgeon for the Matlock District (Derbyshire).

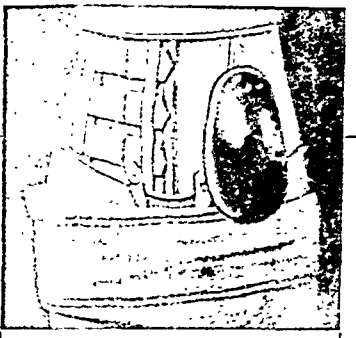
Diary of B.M.A. Central Meetings

JANUARY

9 Thurs. Journal Board, 2.15 p.m.

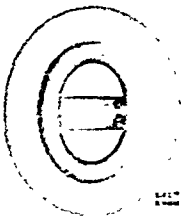
BIRTHS, MARRIAGES, AND DEATHS

The charge for inserting announcements under this head is 10s. 6d. This amount should be forwarded with the notice, authenticated with the name and address of the sender, and should reach the Advertisement Manager not later than the first post Tuesday morning to ensure insertion in the current issue.



DEATH

HENDERSON.—On December 17, 1940, suddenly, at 59, Orchard Avenue, Parkstone, Dorset, William Savile Henderson, M.D.Liverp., B.Sc.Lond., aged 67.

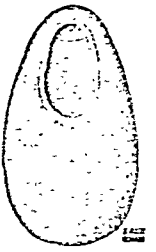


SURGICAL SERVICE
SALTAIR

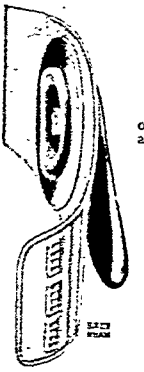
A DISTINCT SUCCESS FROM EVERY POINT OF VIEW:

SALT'S PATENT COLOSTOMY BELT

Showing other views of receiver.



See groove over which aperture in bag is stretched and curved bridge to hold open mouth of bag.



From the points of view of Hygiene, Comfort and Economy, Salt's patent Colostomy Belt has proved a distinct success. The reasons are revealed in the illustrations which depict the special features that collectively make an Appliance that is really efficient. The receiver is detachable and sterilizable by boiling; the bag is easily removed without removal of belt and is easily emptied and washed out; there are no crevices to hold faeces; smell is reduced to a minimum; the bags are easily and economically replaced. Incidentally, the Belt is less bulky than the old style. Doctors are invited to apply for Salt's Corset and Belt Book, which gives fuller details and handy Measure/Order forms.

India-rubber bag which can be detached at will for cleaning.

Showing bag attached to receiver.

Showing attachment of receiver and bag to belt.

Guarantee

"We guarantee to alter exchange or accept the return of any appliance without cost ordered by the Medical Profession, if not found Suitable within fourteen days from date of supply."

PRIDE AND PREJUDICE IN THE TREATMENT OF CANCER*

BY

Sir ALFRED WEBB-JOHNSON, C.B.E., D.S.O., T.D., F.R.C.S., Hon. F.R.A.C.S., Hon. F.A.C.S.

Surgeon to Her Majesty Queen Mary, Vice-President of the Royal College of Surgeons; Surgeon to the Middlesex Hospital

(*Concluded from p. 51*)

The Throat

Cancer of the throat is one of the most dreaded and distressing of the manifestations of this disease, and never have the sufferings of the victims been so vividly described as they were by Kipling in his tragic poem *A Death Bed*:

> "This is a gland at the back of the jaw
> And an answering lump on the collar-bone."
>
> "It will follow the usual course of—throats"
>
> "Since it is rather too late for the knife
> All we can do is to mask the pain."

In studying cancer in this region it becomes clear that one is turning the pages of one of the most brilliant chapters of British surgical achievement.

The Larynx

Discussion of carcinoma of the larynx should be confined to intrinsic tumours, for the so-called extrinsic carcinoma is really cancer of the pharynx. In operative treatment the teachings of Sir Felix Semon and Sir Henry Butlin were brought to their highest standard of success by Sir StClair Thomson. He recorded 70 cases operated on by laryngo-fissure, with only 2 deaths as the result of operation (*British Medical Journal*, 1928, **1**, 743). Excluding those dying of other diseases, 38 out of 55 patients were alive and well from five to nineteen years after operation—a net five-year survival rate of 69%. This is exactly the same as the rate being attained at the Christie Hospital and Holt Radium Institute, where radium is used according to the Finzi-Harmer technique. This figure is arrived at, however, by a follow-up of only 16 cases treated in 1932 and 1933. But in the course of twenty-eight years StClair Thomson operated on only 70 cases, which shows that fortunately the larynx is not a common site for this disease. With these small numbers it is obvious that the problem in this situation does not lend itself well to statistical study, but the figures cited are significant. Other workers claim equal success by external radiation in spite of the barriers of skin and cartilage.

The results of radiation therapy are obtained with practically no disability or mutilation. But it does not do to exaggerate the change of voice produced by partial laryngectomy. A useful voice is preserved, and among StClair Thomson's patients were men who continued to follow professions such as schoolmaster and physician, while one was a parson who preached twice every Sunday. The pitfalls of radiation, such as overdose to skin and necrosis of cartilage, have been largely overcome.

The brilliant results from partial laryngectomy by thyrotomy or laryngo-fissure only emphasize the limitations of operative treatment, for any more extensive operation entails serious mutilation and disability. When only total laryngectomy can be offered by surgery the radiotherapist can often retrieve what looks like an absolutely hopeless position, and in the more active and advanced lesions radiation may be of great value when surgical procedures have little to offer.

The Pharynx

In the case of the pharynx most statistical returns do not distinguish between different types of tumour or even give their exact situation. Reports on end-results in cancer of the pharynx must first of all supply figures for each anatomical site. This would give *some* indication of the nature of the tumour, but it is not enough. The character of the tumour and the histological grading must also be ascertained and recorded, not only for statistical review but also to determine the best line of treatment. The site of origin and the character of the lesion are more important than the extent. The size of the growth is no criterion. A small tumour may lead to disappointment, while a large one may react in a most favourable way. Carcinoma of the tonsil can be cured even if large glandular metastases are present, but quite a small lesion of the anterior pillar of the fauces or the pyriform fossa may be incurable.

Since the tumours range from lympho-epithelioma to hard, warty, localized growths there is a great difference in their radiosensitivity. Exact details of the site and character of the growth are essential, and without these details statistics are valueless. But though we have not these details or statistical proof to guide us in regard to cancer of the pharynx we do know that tumours of the nasopharynx, the valleculae, the pyriform fossa, the deep pharynx, and the base of the tongue can often be made to disappear in a most remarkable manner by radiotherapy. Some of the results of radium beam therapy are most encouraging, but it may be that deep *x* rays can accomplish as much.

In tumours of the hypopharynx, essentially a disease of women about the menopause, an important consideration

* The Bradshaw Lecture delivered before the Royal College of Surgeons of England on November 27, 1940.

is the possibility of prevention. The Plummer-Vinson syndrome may or may not be the direct cause of tumours of the hypopharynx and it may occur without anaemia, but, as Witts has pointed out, the anaemia which is very common in women suffering from these tumours is due to iron deficiency and can be cured by the administration of iron, which not only repairs the anaemia but also restores the epithelium. The cracks at the corners of the mouth heal, the tongue is reclothed with papillae, the epithelium of the pharynx becomes more normal, and dysphagia is relieved.

The Oesophagus

Treatment of carcinoma of the oesophagus by surgery or by radiation has been disappointing, though there have been brilliant isolated successes. The tumour is of the same histological type as carcinoma of the cervix uteri. But here, unfortunately, we are dealing with a canal with thin walls which is immediately surrounded by vital structures. The growth is nearly always infiltrating the wall of the oesophagus when first diagnosed. The tumour is very sensitive to radiation, and its rapid destruction as the result of direct radium treatment often leads to perforation. External methods of radiation are therefore being more assiduously tried. There have, however, been no lasting cures by radiation in proved cases: reports in the literature refer to cases without histological proof and with inadequate periods of observation after treatment. There are some encouraging cases, but many disasters have occurred from serious changes in the lung. It is to be hoped that with further developments in technique greater success will be achieved.

Surgical excision has been attended with a few successes in the hands of bold operators, particularly in cases in the cervical portion and the lowest part, even with preservation of the channel. A few successes have been achieved also after removal of the middle portion. Garlock of New York (*Surg. Gynec. Obstet.*, 1940, **70**, 556) has reported 7 cases, in 6 of which the patient survived the radical operation. Four are still well—one of them two years and eleven months after operation. In Torek's historic case of transthoracic excision the subject lived for thirteen years and died of old age without recurrence. Grey Turner had one successful case, but the patient died of nephritis nineteen months afterwards. Lately Wookey (*Brit. J. Surg.*, 1940, **27**, 696) reported 4 cases of transthoracic removal, in 3 of which he adopted a new technique by approaching through the right side of the chest with ligature of the vena azygos major.

Grey Turner, who dealt fully with this subject in his Bradshaw Lecture of 1935, advises that if the history is short and there is no evidence of secondaries, and if improvement is rapid after a gastrostomy, radical operation should be considered. But our real hopes for the future lie in finding some method by which radiation can be brought safely to bear on this perilous region. The growth itself is vulnerable to attack, but a way must be found to protect the vital parts in the immediate neighbourhood.

Except as a preliminary to radical excision gastrostomy is now seldom required. By the method of intubation introduced by Charters Symonds and so ingeniously improved and applied by Souttar we can bring relief and comfort to and prolong the life of sufferers from oesophageal cancer

The Rectum

Surgical treatment of carcinoma of the rectum, based on the scientific work of Ernest Miles, may attain an 85% five-year freedom rate in Stage A cases, and between 40% and 50% in all cases (Gabriel). For many years efforts have been made to treat the disease in this situation by radiation therapy. Unfortunately the rectal mucous membrane is generally just as radiosensitive as the tumour. Gordon-Watson endeavoured to treat the condition with radium and did pioneer work on the surgery of access, but, as he stated in his Bradshaw Lecture of 1937 (*Lancet*, 1938, **1**, 239), he came to the conclusion that "although brilliant results were obtained in a small proportion of operable cases, the results were too uncertain to justify its use in an operable case with our present knowledge, except when a radical operation is contraindicated on general grounds." He has also reported, however, that although it was only in a small proportion, he had in several instances reduced fixed inoperable cases to a state of complete quiescence, if not cure, and that some of these patients remained in good health for periods ranging from seven to ten years (*Proc. roy. Soc. Med.*, 1935, **28**, 1251). The rare radiotherapeutic successes may be in cases of an undifferentiated type.

Serious efforts are being made to treat the condition by external radiation not only with the usual 200 kV machines but with large radium bombs and *x*-ray plants working up to a million volts. Ralph Phillips has treated a few cases by the latter method at St. Bartholomew's Hospital, and among them he showed me the notes of a patient aged 41 in whom an inoperable growth has been made to disappear and, two years after the treatment was begun, the colostomy has been closed.

The Uterine Cervix

In cancer of the uterine cervix the best British results from operative treatment are those attained by Victor Bonney, whose pioneer work with Comyns Berkeley laid the foundations, in this country, of the sound surgical treatment of that condition. Table II provides a fair basis for comparison between Bonney's five-year figures and those of the Marie Curie Hospital, where the best results have been attained by radiation treatment.

TABLE II

Victor Bonney: Cases operated on up to the end of 1928

Stage	No. of Cases	Gross Five-year Survival Rate
I	212 (no glands)	109 (51.4%) } = 38.8%
II	154 (with glands)	33 (21.4%) }
III		
IV	0	Inoperable

(*Transactions of the Medical Society of London*, 1934, 57, 196)

Marie Curie Hospital: Cases treated 1925 to 1933

Stage	No. of Cases	Gross Five-year Survival Rate
I	40	34 (85%) } 65.7% } = 42.6%
II	170	104 (61.1%) }
III	459	147 (32%)
IV	133	11 (8.2%) Inoperable
Total	802	296 (36.9%)

(Medical Research Council Report No. 236, 1939.)

The operation cases have not been separated into stages on the lines of the League of Nations classification, but if Stages I and II are counted as definitely operable radiotherapy is immensely better than surgical treatment, and even if Stage III cases are included among the operable ones, which is giving a distinct advantage to surgery in the calculation, the table still shows that better results are obtained by radiotherapy.

It is stated that 10% of all recurrences develop after the fifth year, and that therefore only ten-year survival rates should be accepted for a true assessment of results.

Table III shows a comparison of the ten-year survival rates, and again the advantage is slightly in favour of treatment by radiation, although the cases date back to a time when the technique was not as good as it is to-day.

TABLE III

Victor Bonney: Cases operated on up to the end of 1923

Stage	No. of Cases	Gross Ten-year Survival Rate
I	156 (no glands)	61 (39.1%) } = 30%
II, III (with glands)	110	19 (17.2%) }
IV	0	Inoperable

(*Transactions of the Medical Society of London*, 1934, 57 195.)

Marie Curie Hospital: Cases treated 1925 (3 Months) to 1928

Stage	No. of Cases	Gross Ten-year Survival Rate
I	10	8 (80%) } = 48.9% } = 30.4%
II	37	15 (40.5%)
III	124	29 (23.3%)
IV	45	2 (4.4%) Inoperable
Total	216	54 (25%)

(Medical Research Council Report No. 236, 1939.)

The results obtained at the Marie Curie Hospital are so good that they naturally stimulate inquiry. It has been said that a large number of the patients are nulliparous women and that maybe some cases were not carcinoma. I found the proportion of nulliparae to be 12%—8% being married and 4% unmarried. This would strike the old teachers of gynaecology as unduly high, but I do not consider it so in a hospital staffed by women, for at a general hospital like the Middlesex, taking the cases for 1936, 1937, and 1938, there were 11 nulliparae among 118 patients with carcinoma of the cervix, or 9.2%, and 4 of the patients were unmarried. It is said that a large proportion of early cases go to the Marie Curie Hospital, but in actual fact the proportion of Stages I and II cases is very low. It is also said that maybe this hospital receives selected cases only, because several unsuitable cases are not sent for treatment; but I am informed that *all* cases seen by the surgeons at their other hospitals are referred to the Marie Curie Hospital for radium treatment, with the sole exception of the Royal Free Hospital, from which *every* third case is referred. The success of the hospital is really due to the following factors. It is very well equipped, the staff is extremely expert, and there is a large personnel; but the most important factor of all is that the most meticulous care is taken in carrying out the treatment, in following exactly the selected technique, and in making every effort to improve the local and general condition of the patient before radiation treatment is undertaken. Comparable results are obtained at other first-class radiotherapy centres, and the figures in Table IV of a general hospital like the Middlesex, with a large radiotherapy department, are also interesting. All the cases were seen first by the gynaecologists, and it may fairly be assumed that Bonney and his junior colleagues, both of whom were his pupils, would have a predilection for operative treatment unless there was some local or general contra-indication.

TABLE IV.—*The Middlesex Hospital, January 1, 1932, to June 30, 1935*

A: Operation Results

Stage	No. of Cases	Gross Five-year Survival Rate
I (no glands)	39	16 (41.0%) } = 38.4%
II, III (with glands)	13	4 (30.7%) }
IV	0	Inoperable

B: Radiotherapy Results

Stage	No. of Cases	Gross Five-year Survival Rate
I	9	6 (66.6%) } = 44% } = 34.9%
II	16	5 (31.2%) }
III	38	11 (28.9%) }
IV	35	3 (8.5%) Inoperable
Total	98	25 (25.5%)

The numbers are not large enough for statistical study, but they are distinctly significant. In Stage I and II cases the radiotherapy results are better, but when Stage III cases are included as operable the percentage advantage is with surgery. But only one-quarter of the radiotherapy cases were Stage I and II and less than a half when Stage IV cases are excluded, whereas three-quarters of the operation cases were Stage I. Moreover, the radiotherapy cases included 4 of palliative *x*-ray treatment and 5 treated by radium only and judged to be unfit for the full course; while 14, with only 1 five-year survivor, were treated before the Paris technique was adopted.

The operative mortality still remains in the neighbourhood of 10%, to which Bonney reduced it in favourable cases. The dangers of radiotherapy, which at first were a serious consideration, have been so mastered that at the Marie Curie Hospital only 2 cases of fistula have been seen in the last 700 cases.

Study of the available figures leads to the conclusion that better results can be obtained by radiotherapy than by operation in cases of carcinoma of the uterine cervix.

As a final consideration it is well to bear in mind that the radical operation for carcinoma of the cervix is one of great difficulty and that few can attain the results of Bonney and his colleagues. Radiation treatment, on the other hand, can be copied with meticulous care, and, provided the staff and equipment are adequate, good results should be attainable in many centres. Some cases do not respond to radiotherapy. They should be submitted to operation without delay, and they serve to emphasize that the course of safety is for surgeon and radiologist to work together.

The Breast

Consideration of cancer of the breast naturally calls to mind, among men of our time, the names of three of the seven Walker Prizemen of our College—Harold Stiles, Sampson Handley, and Lenthal Cheatle—who have devoted a large part of their lives to the study of this condition. The results of operation in Stage I cases are excellent. In the thorough and capable hands of Gordon-Taylor an 84% ten-year survival rate has been attained in cases traced from ten to twenty-five years. In more advanced cases, however, the results are most disappointing, and it is terrible to reflect that if the axillary glands are involved over 60% of our patients die of the disease within five years of operation.

In order to avoid the mutilation from which patients naturally recoil efforts have been made to ascertain whether radiation could safely be recommended as a substitute for surgery in Stage I cases, but the results achieved do not justify such a course. Keynes's efforts to attain by radium implantation results comparable to surgery were a real contribution to technique, but they revealed the limitations of radium implants with their localized action. The area to be dealt with is very extensive, and Keynes himself has realized that external radiation has advantages over implantation.

When considering reports of favourable results from external radiation alone it must be remembered that the recorded cases are few, that as a rule the diagnosis is not

proved by pathological investigation, and that in early cases there is no unequivocal sign which will enable the clinician to make a diagnosis with absolute certainty. Nevertheless there is no doubt that successful results can be obtained, and if operation is refused or contraindicated radiation treatment is justified in Stage I cases.

In seeking for assistance from radiation therapy while still practising surgical excision, attempts have been made by pre-operative or post-operative, or by pre-operative *and* post-operative radiation to reinforce the attack on the disease. In favour of pre-operative radiation it may be said that it demonstrates which cases are radiosensitive, and these are just the ones in which radical surgery is likely to fail. It also decreases the vitality of the cancer cells previous to operative disturbance. It may interfere with healing, but this is minimized by proceeding to operation directly the pre-operative course is completed. In regard to post-operative radiation, it has to be remembered that after operation the tissues will not stand a full dose owing to the surgical trauma and the impaired blood supply; and nothing less than the full dose is likely to be really effective. Figures from some centres indicate that a combination of pre-operative and post-operative treatment may be the best.

The view is held by some that radiation alone may be the best treatment in Stage II and Stage III cases. In its favour it is argued that a full dose of radiation can be given without interruption, and that the radical operation is often dangerous, as it involves the risk of cutting into cancerous tissue in the axilla. But we have no convincing statistics to prove that the results of radiation are better than those of operation. Mass statistics, with percentages often based on an insufficient number of cases, are quoted in support of radiation treatment, and even averages of percentages (a most fallacious use of statistics) are marshalled in further support. Our experience at the Middlesex Hospital would not permit us to subscribe to this view.

It may be that we have had enough of statistics based on large series of cases treated on certain definite lines and that what is required is that each case should be treated in the way which appears best after considering all the circumstances. We may thus ascertain whether, with the exercise of judgment, the gross results can be improved, and then, by analysis of those results, find out which treatment is best for each class of case.

Our accumulated experience seems to me to justify us in regarding each case at the outset as a radio-surgical problem, and then proceeding as follows:

In a *clinical Stage I* case give a short intensive course of radiation. If the tumour shows signs of disappearing rapidly it is very radiosensitive and likely to be unpromising for surgery. Radiation should therefore be continued. If the response to radiation is not very striking, then radical operation should be undertaken immediately after about a third of the full dose has been given. The specimen should be examined with meticulous care, and further procedure planned on the two alternative results of the investigation: (1) if there is no evidence of extension to the glands the case is pathologically proved to be Stage I, and no further radiation is indicated; (2) if, on the other hand, the glands are found to be involved the case is pathologically Stage II, and the course of radiation should be completed. Some of the 60%. of failures after radical operation in Stage II cases might be saved by this post-operative completion of the radiation course.

If the case is *clinically Stage II or Stage III* radiation treatment is definitely indicated at the outset. A good response would encourage continuance of radiation, for on biological grounds the case is probably unsuitable for operation. If, on the other hand the response is not good, or there is a residual lump, the breast should be removed without opening the axilla. Radiation treatment should be completed after operation, for glandular deposits are more constantly made to disappear than the primary growth. The risk of disseminating the disease that is involved in clearing the cancerous contents of the axilla would be avoided by this procedure.

Finally, there is no question of the good that radiotherapy does in some advanced cases in this and other situations and also in the case of some metastases, but it must be admitted that in others it only adds to the patients' sufferings. Radiotherapists should therefore never be pressed to give treatment as a placebo or in cases that are obviously hopeless.

The Cancer Act

From a study of the present position of cancer treatment certain points are clear: first, that about half the patients suffering from cancer need some form of radiation therapy; second, that this difficult work can only be undertaken satisfactorily under the most favourable conditions; and, third, that intensive research is required in every aspect of the cancer problem.

The first two requirements are not being met, for it is estimated that in this country only about a quarter of the sufferers obtain treatment of a skilled nature at hospitals adequately equipped and staffed, and that where diagnosis requires highly technical investigations the proportion is smaller. The Radium Commission made repeated and urgent representations that to secure a reasonable standard of service for the treatment of cancer cases throughout the country there was need for the Government to attack the whole problem along national lines. The Cancer Act is designed to achieve this object. By March, 1942, local authorities, co-operating if necessary with neighbouring authorities, have to submit schemes for the approval of the Ministry of Health, making arrangements to secure that the facilities for the treatment of persons suffering from cancer are adequate for the needs of the county or borough. We are therefore on the eve of a great development of regionalization of hospital services for this specific purpose, and those studying the question of regionalization will do well to bear in mind this particular need, for it may be found that the arrangement of localities necessary for the cancer service will be suitable for other purposes also. Under the provisions of the Cancer Act local authorities are empowered to make grants for extensions of voluntary hospitals and for the maintenance of those extensions. Those who fear for the future of the voluntary hospitals should note the words of Sir Arthur MacNalty, who, when Chief Medical Officer of the Ministry of Health, said that "only by co-operation in hospital services regionally and nationally will the difficulties of expense of voluntary hospitals be overcome and the voluntary principles of which this country is so proud be safeguarded."

Cancer Centres

In an explanatory circular issued to local authorities in May, 1939, it is explained that the provision of adequate facilities for cancer treatment means both by surgery and by radiotherapy, including treatment by radium and by deep *x* rays. This is satisfactory, for it makes it clear that the centres are to be Cancer Centres and not just Radium Centres. The Minister's view was expressed that treatment must necessarily be concentrated in those comparatively few hospitals which have on their staffs skilled radiotherapists and physicists as well as surgeons, which possess the requisite specialized departments, and which contain enough beds to keep the radiotherapeutic department, with its expensive equipment of radium and apparatus, fully employed. The Minister hoped that there would be full co-operation between the authorities and the voluntary

hospitals, and he enjoined that the hospitals which already hold supplies of radium and which otherwise possess adequate facilities should be utilized to the greatest possible extent.

The Minister pointed out that surgical operation still remains the only practicable, or the most suitable, form of treatment for a large proportion of cases, and that for this purpose it may be found necessary to make use of some hospitals in which radiation treatment is not available. He lays down the condition, however, that "where use is made of such a hospital a patient should be treated there only when it has been decided, after consultation between the appropriate specialists, that surgery without radiation is the proper form of treatment for the case." This applies to at least half the patients receiving treatment. Is such an instruction justified by the present state of our knowledge? And, if so, should not a similar consultation be required before radiation treatment is allowed? In point of fact it is certain that there are not enough experienced radiotherapists available for such consultations.

One of the most important matters to ensure the success of the scheme will be proper central control. It may be true that the Ministry is to appoint an expert advisory committee with representatives of medicine, surgery, gynaecology, radiotherapy, pathology, and public health, and that this expert committee dovetails with the Medical Advisory Committee of the Ministry, which includes the Presidents of the three Royal Colleges. Such Advisory Committees are often chosen but seldom called. The real work will be done by an executive body, and in my view that body will be best equipped for its task if it is made directly responsible for the management of a National Centre. It will then be in constant and immediate touch with those actively engaged in treatment and research. The National Cancer Centre would also be the appropriate place for the establishment of a central bureau for the collection and study of records.

The provision of adequate facilities for cancer treatment entails the establishment of several centres in addition to those already recognized as efficient, and it is estimated that at least a thousand additional beds will be needed. The establishment of hundreds of consultation centres for diagnosis and for the following up of patients will be required, and in this way the essential link between general practitioners and hospitals will be provided.

Each centre must be a fully equipped hospital or branch of a hospital specially devoted to this work. It must have plenty of beds, and it must have rooms for private patients. In the future, even more than in the present, treatment of this disease will have to be carried out in institutions, and all classes of the community must be eligible for admission. There must be an expert staff and every facility for diagnosis and treatment. There must be a full-time radiotherapeutic staff with at least two experienced members. There must be ample radium, so that all methods of application can be employed. There must be a generous equipment of *x*-ray apparatus, so that treatment and dosage can be prescribed and spread as the radiotherapist requires and not just meted out so that all who demand shall share in what is going. There must be a large staff, so that treatment can be supervised and cases carefully studied. There must be an expert surgical staff, carefully chosen for their special aptitude in diagnosis and operative skill in various regions. There must be well-staffed and well-equipped departments of pathology and physics. There must be well-paid posts for assistant members of the staff, and facilities for those undergoing training, so that there will be a plentiful supply of radiotherapists to fill senior posts as they fall vacant.

Medical Education and Research

When schemes are submitted for approval two aspects of the proposals will be of special concern to our College. One is that facilities for medical education shall be safeguarded, and the other that research shall be encouraged.

In regard to medical education, it must be remembered that, while the treatment of cancer may be very special work requiring much postgraduate study and experience, instruction in diagnosis together with the observation of the results of treatment is essential for the undergraduate. The success of a cancer service depends on early diagnosis, which depends in turn on the recognition of the significance of symptoms, and for this purpose the general practitioner is the first essential link in the chain. Every medical school, therefore, if not a treatment centre, must be a consultation centre for diagnosis and for observation after treatment.

In the Cancer Act no provision is made for research, but the treatment of cancer can be carried on efficiently only in a spirit and atmosphere of inquiry, and if any centres are planned without regard to the need for research the work at those centres will not be of the highest standard and they will fall behind in the effort to bring relief to sufferers from this disease.

In clinical research the records department will assume greater and greater importance, for more detailed returns will be required. Every case should have a record of the exact site, extent, and duration of the lesion, and there should be an agreed "staging" for all sites. The records should include *exact* details of the histology, and the tumour should be carefully graded. Uniformity in methods of making returns is essential.

Immediate Needs

The Cancer Act provides a splendid opportunity. Great hopes are founded on it, but their fulfilment will depend on the genius and foresight of those responsible for carrying out its provisions. Regional schemes cannot be formulated for some time, but there are two urgent needs which should be provided for without delay. As already mentioned, one urgent need is the formation of a central national authority to study the problem and guide local authorities; the other is provision for the training of personnel.

There is a serious shortage of trained personnel, and in my opinion those already experienced in this work should be released from the Services and those anxious and fitted to take up the practice of radiotherapy as a career should be reserved from mobilization.

To fit himself for a career as a radiotherapist a graduate first requires to attain the standard of one of the higher surgical qualifications. He needs at least twelve months' training at a recognized centre, and must obtain a special diploma in radiology and later the higher diploma of the Faculty. But the only training worth while is experience—like the apprenticeship served to medicine and surgery and several specialties. Postgraduate courses are useful for obtaining the hall-mark of a diploma, but responsibility under supervision is the real training. The trainee should therefore hold a resident post in a cancer department, and, before having independent charge of patients, he should serve for about three years in an appointment equivalent to that of a registrar or first assistant. It is obvious, therefore, that the junior posts must carry generous remuneration, that there must be good prospects of promotion, and that the higher positions must be equal to those in any other branch of the profession.

The director's post must carry the full status of a staff appointment. In university centres he should be given

professorial rank, and he should not be barred from private practice in the institution. This can easily be limited by the number of private beds at his disposal. The best men will get the best results, and they are entitled to their reward both in professional status and in income. However lavish may be the provision of armamentarium, in radiotherapy as in surgery it is "the man behind the gun" that counts.

Conclusion

It is twenty-three years since I had the honour of delivering a Hunterian Lecture in our College. That too was in wartime. On that occasion I told the story of the conquest of the hosts of death—of the taming of the typhoid group of organisms by protective inoculation. Many other diseases have been controlled and almost conquered in our time, and even during the last twenty years of peace. I have no doubt that cancer will be added to their number. The possibilities opened up by recent research increase our confidence in ultimate success.

But until many questions are answered and we are armed with full knowledge of the cause of this disease, and thus on the way to prevention, we have to face the task of giving the best treatment to relieve and, as I have shown, oft-times to cure. I hope I have said enough to show that in addition to proved and trusty means of treatment we have powerful new weapons with which to combat the disease: but they are powerful for evil as well as for good, and need skilled and experienced control. I have emphasized, therefore, that the training of more men and women to use these weapons should be undertaken without delay. It is obvious that in the future there must be closer co-operation between surgeons and radiologists if we are to do the best for our patients. Special tumour clinics should be arranged: teams should be carefully chosen and certain regions assigned to special surgeons. A competent team must include surgeon, radiologist, pathologist, and physicist. It is abundantly clear, therefore, that there is urgent need for far greater facilities and a large army of workers.

I have spoken of the sturdy heroic work which has been done in the past and of the successes which have been achieved, but in our College we are only too well aware of the gaps in our knowledge and of the colossal amount of research work still to be done.

"And here will I make an end, and if I have done well, and as is fitting the story, it is that which I desired"—not only because of the vital importance of the subject, but also because I wished to do honour to William Wood Bradshaw, by whose devoted widow this Lecture was founded. But whether I have done well or ill, I hope I shall be acquitted of ungraciousness if I observe that, greatly as I appreciate the honour done me, much of my Lecture goes to show that those who in the future may be disposed to make benefactions to our College will do a greater service to humanity and ensure a richer harvest from their gifts by providing endowments for research than by founding eponymous lectures to be delivered within its walls.

O Witt Mitchell and O. D. Chapman (*New York State J. Med.*, 1940, **40**, 1308) record thirty-eight cases of *Staphylococcus aureus* septicaemia in patients aged from 3 to 65. Thirty-one were males and seven females. Twenty cases were examples of cellulitis, boils, or carbuncles, and eighteen of osteomyelitis, which with three exceptions were all in children. Half the patients with cellulitis, boils, or carbuncles had primary lesions on the neck or face. Of the osteomyelitis cases the tibia was the first bone to be involved in nine and the femur in six. Fifteen of the patients with primary lesions and seven of the patients with osteomyelitis died.

A SURVEY OF NUTRITION AND DENTAL CARIES IN 120 LONDON ELEMENTARY SCHOOL CHILDREN

BY

IRENE ALLEN

University College, London

Assistant to the late Matthew Young, M.D., D.Sc.

A radiological investigation to study growth in school children was being carried out at University College by the late Prof. Woollard and the late Dr. Matthew Young which necessitated the six-monthly examination of 200 elementary school children between the ages of 5 and 8 years. It was hoped that this investigation would throw some light on the problem of nutrition.

In addition to the taking of radiographs the children were weighed and measured (without shoes), and various other clinical notes were made. It seemed of interest, to complete the picture, to have some information on the condition of the teeth, so a quick examination was made, and the findings form the subject of this survey. The period covered was one year, during which they were examined three times, although only the first and third inspections are considered here. As usually happens in this kind of investigation the numbers of children available dwindled considerably by the end of the year. Those examined appeared to be in fairly good physical condition on the whole and most of them had had extra milk at school.

When making the dental examination the buccal surfaces of the teeth were first tested with a probe for structural defects as shown by varying degrees of roughness, pits, etc., and graded into four categories. The grading was, so far as the personal factor allowed, similar to that used by M. Mellanby. Perfect smoothness of surface was graded as normal or category 0; and to categories 1, 2, and 3 were allotted teeth showing slight, marked, and severe roughness and pitting. It must be emphasized, to avoid misunderstanding, that the types of defects referred to here are those first recognized by M. Mellanby (1923, 1927, 1934) and included by her under the heading of "hypoplasia"; they are much more common, though less obvious, than the generally recognized gross type and present a different microscopical structure. In a dental survey J. D. King (1940) distinguished between the two kinds by calling them "M-hypoplasia" and "G-hypoplasia" respectively, and whereas it has been proved by many observers (Mellanby, King, Hughlings Davies, etc.) that the former type is to be found associated with dental caries, there is some doubt as to whether any association exists between dental caries and G-hypoplasia—in fact, King could find no association between these two conditions in the children examined by him in the Island of Lewis.

Having graded the structure of the teeth, the amount of caries was then noted. Owing to lack of time it was not possible to explore every tooth thoroughly with the probe; the teeth were also in some cases very dirty, so that very early caries must have been overlooked. The carious teeth were graded roughly into three categories, according to the size of the carious area: caries 1 included teeth with cavities up to about the size of a large pin's head; caries 2 included those with cavities larger than grade 1 but involving less than a third of any one surface; and caries 3 included all teeth with cavities involving more than a third of one surface. This method is admittedly rough and the grading arbitrary, but it serves to give an indication of the amount of spread of caries over a period of time, and when assessing the amount of caries per mouth is much more satisfactory than giving a mere percentage of teeth carious, which makes no allowance at all for the size of the carious cavities.

The dental examination was made by me and the observations were taken down at dictation by a second person. A complete survey was first made of the mouth for structural defects, then a second round of the teeth was made to assess

caries, by which time the figure assigned to any particular tooth for M-hypoplasia had been forgotten; the two sets of findings should therefore be quite independent.

Structural Defects (M-hypoplasia)

An average hypoplasia figure was first calculated for each type of tooth to see how the structure compared one type with another (see Table I); this figure is obtained by adding up the marks allotted to all the individual teeth and then dividing by the total number of teeth.

In Table I the types of teeth were arranged in ascending order of the average hypoplasia figures at age 5; the

TABLE I

	Age 5 (34 Children)		Age 6 (55 Children)		Age 7 (32 Children)	
	Total No. of Teeth	Average Hypoplasia* Figure	Total No. of Teeth	Average Hypoplasia Figure	Total No. of Teeth	Average Hypoplasia Figure
Lower:						
Lateral incisors	64	0.23	81	0.26	22	0.32
Central ,,	59	0.27	30	0.53	14	0 29

2nd ,, ,,	68	1.69	91	1.77	50	1.68

* The term "hypoplasia" is used to cover all degrees of surface structural defects, from very slight to severe, of the type known as "M-hypoplasia."

figures for ages 6 and 7 were subsequently added, and were found to be in much the same order. The teeth showing the best structure are the lower incisors and canines, and the worst are the molars—the upper incisors and canines being intermediate. The earliest-formed teeth are therefore those which have the best structure.

It was desired to ascertain whether in these children any association existed between the quality of the structure of the teeth and the amount of caries present in them. Each individual tooth was considered in relation to the two conditions, and the resulting figures for all the teeth were arranged in the form of fourfold tables for incisors and canines together and for molars. Values for χ^2 and P were then obtained. It will be seen from Table II that all the values for P except one are less than 0.01 (the exception being 0.05 for molars at age 7), showing that such distributions would occur by chance less than once in 100 times (or 5 times in 100 for age 7 molars). A value of 0.05 is usually taken as the level of significance, all values of 0.05 or less indicating a real difference between observed values and such as might occur by chance. It is evident, therefore, that an association did exist in these children between the quality of the structure and the amount of dental caries—the better the structure the less the caries.

TABLE II.—*Association of Caries and Surface Structural Defects (M-hypoplasia) of Deciduous Teeth*

	Age 5 (34 Children)			Age 6 (55 Children)			Age 7 (32 Children)		
	χ^2	n	P	χ^2	n	P	χ^2	n	P

1st and 2nd molars	24.450	1	<0 01	32.982	1	<0.01	4.532	1	0.05

Dental Caries and Nutrition

As already stated the chief point of interest in planning the main investigation was nutrition, and as it was desired to correlate the amount of dental caries present with the nutrition, it was necessary to assign a numerical value to both in every individual.

The difficulty in devising a value for the dental condition is that a figure based only on the teeth present in the mouth at the time of examination is obviously not truly representative of the dental condition of a child who has had a considerable number of teeth extracted for caries. Consider, for example, a child of 5 with only its non-carious incisors and canines left, all molars being missing: unless some allowance is made for the molars which will almost certainly have been extracted for caries at this age, the caries figure for this child will be exactly the same as that for one having a complete set of non-carious teeth. To overcome this difficulty, when assessing the caries *per mouth* it was assumed that in these children (aged 5 to 7 years) all canines and molars missing had been carious in the third grade, and adjustments were accordingly made in the caries figures. Incisors lost might have been carious, but at these ages they might have been shed normally, so no allowance could be made for them. (The age 5 group was the least affected by this consideration, most of the teeth being actually present in the mouth—see Table I—and age 7 the most affected; therefore, age 5 group would give the most satisfactory data.) The carious marks allotted to deciduous teeth in each mouth were added together, then divided by the total number of teeth; this gives an average caries figure which can be correlated with any other condition as required. (Deciduous teeth which were present in the mouth at the first inspection but were shed or extracted during the course of the year were nevertheless included when calculating the final average caries figures in order that the increase in caries might be assessed in the same number of teeth over the whole period.) No account was taken of any permanent teeth.

The assessment of nutrition is a subject on which there is little agreement from any point of view. Standards of good and bad nutrition vary from one clinician to another, and sometimes even for the same clinician variations may be found in the standards used over a period of time. Many factors are involved and much depends on the order in which children are seen, well-nourished ones tending to make less fit ones examined subsequently seem even worse than they probably are, and vice versa. In an effort to produce some standard less influenced by the personal factor, many indices of nutrition have been devised based on various physical measurements. R. Huws Jones (1938) described investigations carried out to test the value of a number of these indices in relation to clinical assessments of nutrition in the same children. It was found that a simple index based on weight/height agreed as closely as any of the more complicated indices with the clinical assessments; moreover, it did not show a greater variation from the latter than that which occurred in the clinical diagnoses of the same children made by different physicians.

In order, then, to obtain a numerical value to represent (however roughly) the state of nutrition in these children it was decided to use the formula:

$$\frac{100 \text{ weight in kg.}}{\text{height in cm.}}$$

Average caries figures and nutrition indices were calculated for the first inspection and again at the end of one year, as well as the differences in each over the whole period. The correlation coefficients obtained are shown in Table III.

TABLE III

	Age 5 (34 Children)	Age 6 (55 Children)	Age 7 (32 Children)
A.C.F. at 1st insp. with 100Wt./Ht. at 1st insp.	0.127±0.169	−0.075±0.135	0.154±0.175
Increase in A.C.F. with 100Wt./Ht. at 1st insp.	0.059±0.173	−0.106±0.135	−0.195±0.173
Increase in A.C.F. with 100Wt. Ht. at last insp.	−0.233±0.165	−0.133±0.135	−0.196±0.173
Increase in A.C.F. with increase in 100 Wt./Ht.	−0.483±0.136	−0.261±0.129	0.028±0.179

At age 5 there is a fairly high negative correlation (−0.483) between the increase in the average caries figure

and the increase in the nutrition figure; that is to say, the *greater* the increase in the nutrition index (indicative of improvement in nutrition) the *less* the increase in caries. At age 6 the same relation exists: the correlation figure is rather low (−0.261), but it is significant statistically, being more than twice its standard error. At age 7 no correlation was found between the two conditions, but, as explained, this group is not so satisfactory because many of the deciduous teeth were already shed.

No association existed between the amount of caries found at the first inspection and the weight/height index at that time. Again, when the increase in the average caries figures was correlated with the weight/height index at the first inspection and at the last, no association could be found between them at any age. This was perhaps to be expected, as these indices only give an indication of nutrition at the time when taken and are not necessarily representative of past physical conditions which may have helped to produce defective and carious teeth, whereas the difference found to occur in the nutrition indices over a period shows what change, if any, is taking place in the child's physique during that time and whether its increase in weight is keeping pace with its growth in stature. It is interesting, however, to note that eight out of the twelve correlation coefficients calculated are negative, showing that the trend is frequently in the same direction—i.e., the better the nutrition the less the onset and spread of caries.

Conclusion

To sum up, it has been shown that, owing to the fact that the nutrition of an individual may vary from time to time, it is extremely difficult to relate it to any other condition at any given period; the complete picture from birth onwards is required. With the knowledge now in our possession, however, it is possible to fit together some of the pieces in the dental picture. It has been shown conclusively in animals that good dental structure can be produced by dietary methods (Mellanby, 1929), and in the investigations carried out in Birmingham by the Dental Disease Committee of the Medical Research Council (1936) there were indications (nursery school) that the same was true for children. Good structure, making the teeth more resistant to disease, is, then, the first line of defence. Post-eruptive influences, though less strong, appear to provide secondary protection, but it is not known how they are exerted. In Birmingham (where the average age of the children was higher than in this series) it was shown that vitamin additions to the diet *before eruption* of the teeth had a definitely beneficial effect in reducing the amount of decay which developed, and also that these dietary additions, even when given after *full eruption*, tended to delay the onset and spread of caries in the permanent teeth. In extension of these findings the present survey would appear to suggest that even in children who have not received any special dietary treatment an improvement in general nutrition, as gauged by the weight/height index, is found in conjunction with increased resistance of the deciduous teeth to dental disease.

Summary

120 elementary school children were examined over a period of one year for dental caries and surface structural defects of the teeth. It was found that:

(1) The lower incisors and canines showed the best surface structure and the molars the worst, the upper incisors and canines being intermediate: the structurally soundest teeth are therefore those of which the greatest part is formed *in utero* before dietary deficiencies are normally felt by the child.

(2) A definite association existed between the quality of the structure of the teeth and the amount of caries present: the better the structure the greater the resistance to dental disease.

(3) An improvement in physical condition as judged by an increase in the nutrition (weight/height) index at ages 5 and 6 was found to be fairly strongly associated with a smaller increase in dental caries.

ANAESTHESIA FOR MAJOR DENTAL SURGERY

AN ALTERNATIVE TO THE ENDOTRACHEAL METHOD

BY

WILLIAM W. MUSHIN, M.B., B.S., D.A. (R.C.S.)
Honorary Anaesthetist, Seamen's Hospital, Greenwich, and Central London Throat, Nose and Ear Hospital; Anaesthetist, Royal Dental Hospital; Anaesthetist, E.M.S.

Pernasal endotracheal inhalation anaesthesia is now firmly established as a method of choice for major dental and oral surgery. It has, however, long been felt that in spite of the obvious advantages attached to the method the liability to trauma of the mouth and pharynx would make a simpler but equally satisfactory alternative desirable for major dental surgery. The oral surgeon expects his patient to be "well" soon after the operation is over, because both he and the public, with a certain amount of justification, do not regard the removal of an impacted wisdom tooth or a cosmetic dental operation, in an otherwise healthy person, sufficient reason for a convalescence of several days or more to recover from the effects of the anaesthesia or from the operations of the anaesthetist.

To obtain the minimum of post-anaesthetic sequelae the anaesthetist must avoid the deeper planes of anaesthesia—the first plane of the third stage is all that is necessary for this work; trauma to the mouth and pharynx; lipoid-soluble agents—nitrous-oxide–oxygen is still the most suitable one for the type of surgery involved.

Advantages and Disadvantages of Endotracheal Inhalation Anaesthesia

Before describing alternative methods the advantages and disadvantages of the endotracheal route will be briefly stated so that comparison may be made.

Advantages.—(1) A perfect airway is obtained which is not obstructed by altering the position of the head or by depression of the lower jaw. As a result the patient breathes quietly and without effort. (2) There is no danger of inspiration of blood, mucus, or operative debris, because the oral pharynx can be packed with gauze or an inflatable cuff round the tube can be used. (3) The mouth is left as a clear field for the surgeon to work in, with no anaesthetic apparatus to get in his way. (4) The anaesthetist is able to stand some distance away from the patient and still maintain efficient observation and control of the anaesthesia. (5) Post-operative vomiting is reduced, because if a lipoid-soluble agent has been used direct impregnation of the saliva during maintenance is reduced. (6) Air is easily excluded, enabling nitrous-oxide–oxygen to be used exclusively and without pressure.

Disadvantages.—(1) Under the light anaesthesia used for dental work considerable skill is necessary to pass the tubes blindly and without trauma into the trachea. (2) It is sometimes necessary to use ether or other lipoid-soluble agent to perform laryngoscopy if blind intubation is not successful. (3) There appears to be an increased liability to post-operative pulmonary complications (Dawkins, 1937). (4) The possibility of trauma to the mouth or throat (Gould, 1935; Clausen, 1932). From the patient's and also to a large extent from the surgeon's point of view the greatest disadvantage of the endotracheal method is the post-operative "sore throat" which sometimes results. Careful observation and questioning of 1,500 consecutive cases revealed that minor discomforts occurred more often than had been previously admitted. In all these cases great care had been taken to avoid rough handling, unclean tubes, dry gauze, and unnecessary instrumentation. In 15% the operation was outside the mouth (i.e., cases for which the operation *per se* could not be blamed). When carefully questioned on the day after operation nearly 10% of these patients complained of *some* symptom. This was usually trivial from a medical point of view, but was often distressing to the patient. The symptom was either "dryness of the back of the throat," "a tickling feeling over the soft palate," or definite soreness over the palate and back of the mouth. In some the symptoms were more severe, such as difficulty in swallowing and, in one case, hoarseness of voice. In all cases the symptoms cleared up in two or three days with simple palliative treatment or none at all. The cause of the faucial and palato-pharyngeal varieties of "sore throat" appeared to be abrasion of the mucous membrane by gauze packing or bruising by surgical instruments (retractors and suckers). The patient with the laryngitis was an adult whose operation for the removal of an impacted wisdom tooth lasted over two hours. Trauma, infection, or prolonged pressure of the catheter may have been the causal factor. Whatever precautions are taken it seems almost impossible to eliminate completely these "sore throats" in some cases.

Alternatives to the Endotracheal Method

To be satisfactory any alternative inhalation method must permit of the mouth or pharynx being efficiently packed. Nasal nitrous-oxide–oxygen can be used very successfully for dental operations lasting hours. Its disadvantages are: (1) The nose-piece is apt to get in the way of the surgeon, particularly in operations in the upper incisor region. (2) The pharynx cannot be packed, as the airway will be occluded, but packing can be placed around and under the tongue. This is efficient only if performed carefully and if a sucker is in use during the operation. (3) The surgeon must be gentle, so as not to disturb the nose-piece or pack. The method is thus unsuitable for the "heavy-handed" surgeon. (4) The method may be extravagant in gas, as pressures of 10 to 20 mm. Hg may have to be used in some cases to maintain nasal breathing. An intermittent-flow machine such as the McKesson is practically essential. (5) Full premedication must be used to obtain uniformly successful results. This is included as a disadvantage because, although I much favour nasal anaesthesia, many anaesthetists are chary of using the necessary premedication. (6) The airway is easily obstructed by the surgeon. Constant vigilance is necessary on the part of the anaesthetist, who usually has to support the lower jaw throughout the operation.

Nasopharyngeal Use of Nitrous Oxide and Oxygen

The use of pharyngeal tubes is not new. Silk (1919) described a nasal tube almost identical in size with those to be described later. His description of the method of its introduction can still be read with advantage. Silk intended his tube only as an alternative to an oral airway with an open-mask administration. Connell (1925) introduced nasopharyngeal *insufflation* of ether by twin nasal tubes, but the method is unsuitable for oral surgery as the pharynx cannot be packed. Pharyngeal *inhalation* anaesthesia with the pharynx packed was first described by Coburn (1921), who used a rubber tube covered with spiral wire and connected to a bag and expiratory valve. This tube was, however, passed through the mouth.

Nasopharyngeal inhalation of gas-and-oxygen has probably been used at some time or other by most anaesthetists. It has not been adopted as a routine procedure, and the following reasons may indicate some of the causes of dissatisfaction: (1) Usually only one nostril is intubated and air-leaks through the other are difficult to eliminate. (2) The diameter of the tubes used is usually too small to enable the patient to ventilate his lungs adequately. Nitrous-oxide–oxygen anaesthesia is difficult to maintain under these conditions without the use of pressure. (3) The tubes are usually too short, and are easily obstructed by the pack in the mouth or pharynx or by the position of the head. (4) The shortness of the tube makes an efficient pack almost impossible. (5) The use of ether becomes almost inevitable.

A technique has therefore been evolved in which two tubes of as large a bore as possible are passed, one through each nostril. The ends of these tubes lie just beyond the epiglottis and opposite the glottis. The tubes are then connected to a McKesson machine, and the pharynx or mouth is packed with gauze. A state of affairs is obtained which has the advantages of the endotracheal method without most of its disadvantages. The only causes of obstruction of the respiration, if the tubes are the correct length, are spasm of the glottis—a condition rarely seen with nitrous-oxide–oxygen anaesthesia—and depression of the jaw by the surgeon, which can usually be countered by the anaesthetist.

Description of Apparatus

Tubes.—By experiment and checking with laryngoscopic examination two average lengths were determined: for men, 6½ inches; for women, 5¾ inches. The tubing is that used for endotracheal work by Magill (the thin-walled variety) cut with a short bevel (45 degrees). The anaesthetist should be prepared to cut tubes for any individual patient. This will be particularly indicated in children and adolescents, for whom it is no use keeping standard lengths. The measuring is done by rapidly passing the lubricated tube through one nostril and listening at the open end. When the maximum tubular breathing is heard, but before the glottis is actually entered (a point

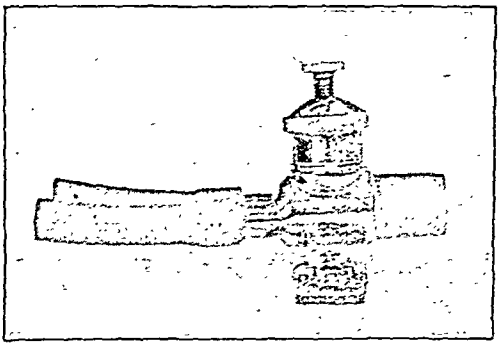

FIG. 1.—The apparatus.

easy to determine with practice), the tube is pinched close to the nostril, withdrawn, and cut.

Connexions.—Two right-angled Rowbotham connectors are used, one in each tube. The connexion to the McKesson machine is by a specially designed Y-piece which has the following features: (1) Each nasal arm is of wide bore (1 cm. internal diameter). (2) A plate covered with rubber to rest on the forehead. This keeps the nasal arms the correct distance away from the face and prevents marking the forehead by pressure of metal. (3) An expiratory valve incorporated in the Y-piece. This was suggested by Dr. de Caux, and avoids a multiplicity of small parts, making for simplicity in connecting up. (4) Two small studs for fastening the whole thing to the patient with an elastic band and avoiding the use of strapping. Fig. 1 shows the apparatus complete.

Technique

The patient is given the usual premedication (I use 2/3 grain of omnopon and 1/150 grain of scopolamine for a normal adult, with occasionally a small dose of evipan in bed). A number of tubes of suitable diameter and length are selected and placed ready, with their right-angled connexions inserted and their ends well lubricated with vaseline. Anaesthesia is induced with nitrous oxide, and when the patient is in deep third-stage anaesthesia the face-

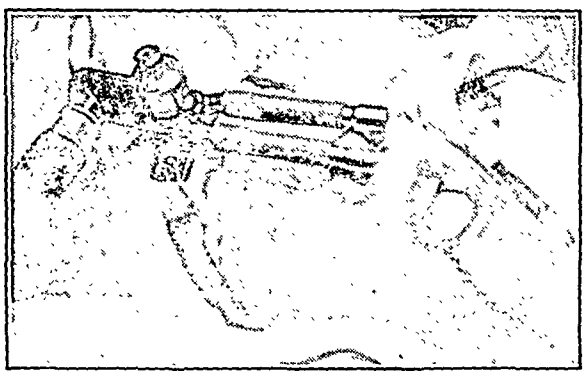

FIG. 2.—The apparatus in use.

piece is quickly lifted and one of the tubes of large diameter (8–10 Magill tube) is passed through whichever is the larger nostril. The tube should be inserted at right angles to the face and the point kept in contact with the floor and septal wall of the nasal fossa. The face-piece is replaced and the patient re-anaesthetized. The second tube is then inserted in like manner. As a rule the two sides of the nose differ in size, and a smaller tube will be used for the other side. The face-piece is discarded and the Y-piece connected up to the nasal tubes and to the McKesson machine (Fig. 2). The patient is now stabilized with oxygen, the pressure of the gases being increased, if necessary, to 10 to 15 mm. Hg to overcome air leakage through the mouth while the pack is inserted. As a rule the mouth can be easily opened at this stage, and the pharynx or mouth packed. If the jaw muscles remain tight secondary saturation may be performed or a little vinesthene added to the mixture. A dental prop should not be used from the start, because it will be found difficult to fit a face-piece over both the open mouth and the right-angled connectors protruding from the nostrils. The packing is of 2-inch ribbon gauze well wrung out in liquid paraffin. It should be carried back beyond the soft palate, so that air leakage does not take place round the tubes via the nares. As a rough guide the anaesthetist should pack in exactly the same way as for an endotracheal tube, but not quite so far back towards the glottis. An equally effective method, but one which is very often preferable, is to use a rectangular gamgee pad of about 3½ by 4½ inches, which is tucked around and under the tongue, reaching back to the fauces on each side. If this latter method is used a sucker is essential.

Results

Altogether 230 patients have been anaesthetized in this manner, the majority at the Royal Dental Hospital, for a variety of dental operations—mostly for impacted molars, dental cysts, and fractures of the mandible. From the surgeon's point of view they were all satisfactory, and in about half the cases he was not aware until after the operation that an endotracheal tube had not been used. Post-operative symptoms which could conceivably be due to the tubes were absent, except in two cases—in one there was an epistaxis twelve hours after operation, and in the other a "blocked nose" for two days. Both these might have been prevented by a more liberal use of vaseline on the tubes or perhaps by a little cocainization. In a few cases in which the jaws could not be opened easily a few breaths of vinyl ether overcame the difficulty. In no case was it necessary to use ether. With the exception of the two mentioned all the patients had completely recovered from the anaesthetic within twenty-four hours and were fit to go home if the local surgical condition allowed.

Contraindications

The method described above has its limitations. In my opinion it is not a satisfactory procedure in the following cases. (1) Large muscular men and patients with short fat necks: depression of the jaw by the surgeon easily obstructs the respiration, and holding the jaw forward to overcome this may be difficult or even impossible. (2) Children under the age of 5 years give better results with endotracheal anaesthesia. In one case adenoids were seen, through a laryngoscope, to obstruct the ends of the pharyngeal tubes. (3) If it is known or discovered that one or both sides of the nose are blocked an endotracheal method is indicated.

Summary of Conclusions

Although endotracheal anaesthesia has many advantages for major dental surgery the occurrence of post-operative sore throat in a number of cases should restrict its use to those in which it is indispensable.

Nasal gas-and-oxygen not being universally applicable, a nasopharyngeal method with the throat packed has been developed.

It has been satisfactory in use to both surgeon and anaesthetist.

It should not be used in patients in whom obstruction due to depression of the mandible is difficult to overcome or in young children.

My thanks are due to the honorary surgical staff of the Royal Dental Hospital for their patience and encouragement during the experimental stages of this study. The special Y-piece was made to my specification by Messrs. A. Charles King of 34, Devonshire Street, W.1.

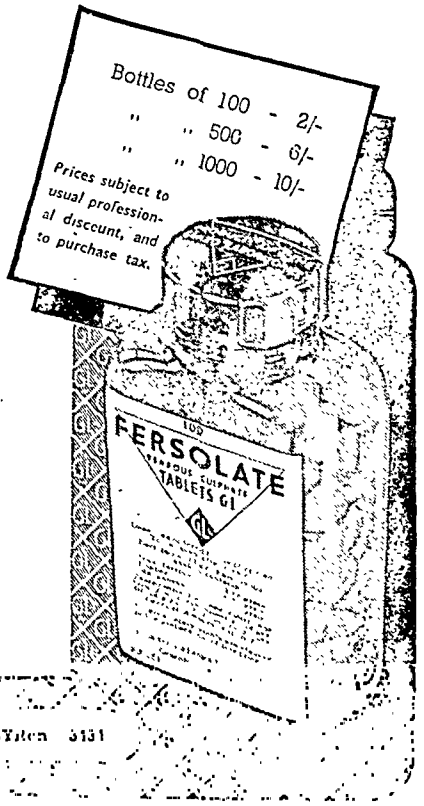
Vitamin routine for every infant

Just as the infant is protected against vitamin C deficiency by a routine ration of orange juice, so he should be provided with extra vitamins A and D by means of some independent standardized preparation. This provision is a wise precaution for all infants, whether bottle-fed or breast-fed. In bottle-feeding the supplement is particularly advisable when liquid or whole dried milk is used. In breast-feeding it is a safeguard to the infant who may be suffering from a maternal dietary deficiency of these vitamins. A daily ten drops of Adexolin Liquid effectively satisfy the infant's dietary needs of vitamins A and D and build a valuable reserve. Powerful assistance is given to normal growth, to dental and skeletal development, and to resistance against infections. Being virtually tasteless, Adexolin Liquid can be given unnoticed in the bottle-feed, or in fruit juice—or even on the infant's tongue.

A 14cc. phial of Adexolin Liquid, costing 2/-, yields 480 drops—sufficient for nearly seven weeks. Even more economical are the 2 oz. bottle (6/-), the 4 oz. (10/-), and the 8 oz. (18/-). Prices (not applicable in Eire) are subject to usual professional discount and to purchase tax.

ADEXOLIN

LIQUID vitamins A and D for growth and well-being



Each cc. contains 12000 i.u. of vitamin A and 2000 i.u. of vitamin D—the equivalent of 20 cc. of medicinal cod-liver oil.

PRODUCT OF THE GLAXO LABORATORIES

Glaxo Laboratories Ltd., Greenford, Middlesex. BYRon 3434

"Iron-rations" must contain IRON

The heavy demands made upon stamina by the national industrial effort must be met. As the pace of production increases, the presence of iron-deficiency anaemia, often undetected in normal times, is likely to become a major problem. Particularly is this so among women workers and juveniles, many of whom already suffer from malnutrition at the outset of their industrial careers. Fersolate Tablets present iron in its most assimilable and effective form—the exsiccated ferrous sulphate, reinforced by traces of copper and manganese. The daily dose of three tablets is therapeutically equivalent to 45 gr. of Blaud's Pills. 1-3 months' treatment, costing much less than a penny a day, is considered effective in almost every case of iron-deficiency anaemia.

OPTIMUM CALCIUM REQUIREMENT

BY

I. HARRIS, M.D.

Honorary Physician to the Liverpool Heart Hospital; Honorary Director of the Liverpool Institute of Research

J. T. IRELAND, B.Sc., A.I.C.

AND

G. V. JAMES, M.Sc., A.I.C.

Leverhulme Research Fellows

The serum of a normal adult is generally considered to contain 9 to 11.5 mg. of calcium per 100 c.cm. Table I gives the calcium determinations of 51 cases taken at random. The blood was examined soon after admission to the Liverpool Heart Hospital. We had no knowledge of the diet calcium of these patients. It will be seen that only in 4 cases out of 51 was the serum calcium below 9 mg.

TABLE I.—*Serum Calcium*

No.	Serum Ca mg./100 c.cm.	No.	Serum Ca mg./100 c.cm.	No.	Serum Ca mg./100 c.cm.	No.	Serum Ca mg./100 c.cm.	No.	Serum Ca mg./100 c.cm.
1	10.1	11	9.2	21	9.0	31	10.0	41	9.7
2	10.3	12	8.4	22	9.3	32	11.7	42	11.2
3	9.4	13	9.0	23	10.4	33	10.5	43	10.1
4	10.4	14	9.1	24	11.6	34	11.0	44	10.4
5	10.1	15	8.4	25	10.2	35	9.8	45	10.6
6	10.0	16	9.6	26	9.5	36	10.1	46	11.5
7	12.0	17	9.8	27	10.4	37	11.7	47	11.3
8	12.9	18	10.5	28	9.5	38	10.8	48	11.9
9	11.6	19	9.1	29	10.5	39	11.0	49	10.9
10	8.9	20	8.4	30	9.2	40	11.0	50	12.0
								51	10.4

The question arises how far calcium intake in diet influences serum calcium. In one patient who was kept for fourteen days on a diet containing 1.6 grammes of calcium daily the serum calcium rose from 12.9 to 13.6 mg. and fell below 10 mg. when the calcium intake was reduced to 0.7 gramme a day. But such results are by no means constant. In a good many of our cases a low calcium intake did not lower the level of serum calcium appreciably; for instance, in one patient having a calcium intake of 2 grammes daily for two weeks the serum calcium was 11.6, 10, and 10 mg. in three different determinations. With a calcium intake of 0.26 gramme daily for a fortnight the calcium serum figures were 11.2, 10.4, and 9.5 mg.; although during this period the patient had a negative calcium balance, the output being larger than the intake. While there is a noticeable tendency for serum calcium to fall with low and to rise with high calcium intake, it is clear that serum calcium values are to a great extent independent of the intake. Serum calcium values by themselves can hardly be utilized as a criterion of an insufficient calcium intake.

Calcium Balances

In our experiments patients were put for a period of fourteen days on high and low calcium intake, all other factors, including the nitrogen intake, remaining the same so far as possible. Between the two periods the patients were kept for some time on a normal diet. With an intake of 0.247 gramme the total output of calcium (Table II) was 0.415 gramme. It increased under an intake of 0.349 gramme, and still more so under 0.39 gramme intake. It will be seen that although with 0.39 of a gramme intake of calcium in the diet the intake is still less than the output, the latter is in this instance greater than when the calcium intake was 0.247 gramme. The same applies

TABLE II.—*Percentage Output of Calcium on Various Intakes*

No.	Daily Intake (gm.)	Daily Output			Percentage of Output in Relation to Intake	Daily N Intake (gm.)	No. of Cases
		Urine	Faeces	Total			
1	0.247	0.292	0.123	0.415	168.2	5	4
2	0.349	0.264	0.165	0.429	124.0	10	6
3	0.390	0.368	0.142	0.510	130.3	10	13
4	0.579	0.338	0.132	0.470	83.0	10	6
5	0.824	0.405	0.154	0.559	68.1	25	8
6	1.791	0.623	0.409	1.032	65.0	10	13
7	1.990	0.315	0.282	0.597	30.0	5	4
8	2.566	0.460	0.371	0.831	35.2	25	8
9	2.712	0.442	0.290	0.732	27.0	25	6

when comparison is made between the first and second series of cases. These figures suggest that when the calcium intake is low the calcium requirement values become reduced, for in the first series of cases an intake of 0.415 gramme would make good the calcium loss, whilst in the second series of cases it would require 0.429 gramme to balance the calcium output.

Starting with the fourth series of cases we find that the calcium output is greater in this series taken as a whole than in the first group of cases; but they differ from all the latter in so far as from now onwards the calcium intake is greater than the output. (The actual output in the fourth series of cases is slightly lower than in the third, but the difference is so slight that it does not really count, considering the large number of cases.)

We are now in a position to consider balances between calcium intake and output, particulars of which will be found in Table II under the heading "Percentage of Output." In the first three series of cases there is a negative balance, the output being greater than the intake. In all others the balance is positive, the intake being greater than the outgoings. There is a depletion of calcium in the first three series of cases and an accumulation of the substance in all the others. We may take it that the calcium intake covering optimum requirements is one with neither a negative nor a positive balance. Looking at Table II, this will be found between a calcium intake of 0.39 and 0.579 gramme. This figure agrees quite well with that of Sherman, Rose, and Rose (1920), who found the minimum calcium requirement to be 0.45 gramme a day for an adult. The minimum calcium requirement is probably lower than the figure given by these authors. In our first series of cases under an intake of 0.247 gramme the calcium output was 0.415 gramme, so that the latter amount would restore the equilibrium between income and expenditure. In our experiments on protein metabolism we found that a low protein intake, which at first resulted in a negative balance, if continued for a long period ultimately established an equilibrium. In this way we have obtained equilibria on very low protein intake. Very likely this applies also to calcium. Our experiments with a low calcium intake, however, did not last longer than two weeks.

Negative Calcium Balance

Calcium metabolism is very complicated, a considerable number of factors coming into play, and some of its features are still awaiting clarification. In the long run the organism cannot put out more calcium than it takes in. Ultimately some sort of equilibrium on a lower level of income will have to be established. In cases in which this does not take place a condition resembling osteomalacia must appear. The bones become soft owing to depletion of the calcium deposits. We do not know whether this condition is met with in England. In any case it is very rare. But, apart from this condition, we may be quite sure that ultimately some balance is estab-

lished between intake and output. One of us has made careful inquiries from a large number of patients attending the Heart Hospital in regard to the diet they are in the habit of taking at home. In no one instance was it found that the average calcium intake was below 0.45 gramme daily. In a good many instances the calcium intake was far above this figure—sometimes four or five times greater. Still more significant is the absence of evidence of any kind that adults (pregnant women excepted) suffer from the effects of calcium insufficiency. Rickets and tetany we may safely leave out of consideration. Sometimes in cases of nephritis the blood calcium tends to be low, but in this instance we may be sure it has nothing to do with an insufficient calcium intake. In some cases of malnutrition a low blood calcium is observable, but in these cases obviously it is not the calcium intake alone which is insufficient. One of us has been looking for years for cases of calcium insufficiency in an extensive hospital practice, and latterly in an institution where normal people are examined periodically, but not one case was found. The dental surgeon of the institution just mentioned makes *x*-ray examinations of the teeth as routine: he too was unable to draw attention to one case of calcium insufficiency. None of us remembers seeing a pathological specimen from an adult that exhibits a lesion in which calcium deficiency is a factor. Yet we are assured on the authority of no less a person than Sir John Orr that in about half of the population of this country the calcium intake is below requirements. In other words, every second person we meet is a victim of hypocalcaemia. Well, all we can say is that since this type of malnutrition gives rise to so few manifestations it cannot be such an undesirable state to be in.

Positive Calcium Balance

On a high calcium intake there is retention of this substance. We may be sure that the piling of calcium in the body cannot continue *ad infinitum*. With a positive e the depots of the body are filled to overflowing. what is more important, we have definite evidence in such circumstances tissue calcium is raised, includ- g tissue calcium of the blood vessels. A number of abbits have been kept by us on a diet rich in calcium, and here are the results of the analyses of two aortas.

	Diet	Calcium of Aorta
Rabbit 1	High calcium	16.2 mg./100 gm.
,, 2	,,	16.9 ,, ,,
Control animal	Normal ,,	9.0 ,, ,,

After a certain level of accumulation of calcium is reached an equilibrium must be established between income and output. But the body calcium under such conditions will be higher all round than under a moderate calcium intake. Such is one effect resulting from excess of calcium intake.

Another aspect of high calcium diet is as follows. We have seen that with a high calcium diet calcium is retained; the total output is nevertheless larger under this condition than with a moderate calcium intake. Using the formula of Hill and Bancroft for estimating kidney work, which is

$$A = RT\left[\Sigma\left(C_u \log_e \frac{C_u}{C_b}\right) + \Sigma C_b - \Sigma C_u\right]$$

where C_u = molar concentration in urine of any constituent,
and C_b = ,, ,, ,, blood ,, ,,

we found in one case the work of the kidney—expressed as litre atmos./litre—to be 18.8 on a calcium intake which was only moderately high, whilst on a lower calcium intake it was 5.1. In another case on a calcium intake which was moderately high the figure was 14.0, whilst on a lower calcium intake it was 0.9. We found that calcium comes second only to protein as an important factor in kidney strain. Now it is an established fact (Harris, 1937) that if damaged kidneys are called upon to perform excessive work the blood pressure rises as an adaptation in order to help the kidney to get rid of the products of metabolism. It is evident that every gramme of calcium which is taken unnecessarily will raise the blood pressure in incipient and established cases of hypertony and in turn overstrain the heart, the blood vessels, and the kidney. It must with mathematical accuracy adversely affect the life of the victim.

We know that arteriosclerotic vessels contain more calcium than normal ones. Whether this is simply a secondary effect or whether the condition is helped along by an excessive calcium intake has not been established as yet. It is at present the fashion to disregard diet as a factor in this type of disease; but the above-mentioned findings in the aortas of rabbits fed on diet rich in calcium will take a great deal of explaining away. Long ago it was shown (Jacoby, 1916) that calcium "thickens" the kidney's filter and makes the performance of its function more difficult. According to the Registrar-General's returns, arteriosclerosis is more prevalent among the affluent classes—the people who are in the habit of taking food rich in calcium, and protein too. It is possible that the poorer classes are less prone to this disease because the calcium intake among other types of food is generally lower. It cannot be said that as yet the evidence conclusively establishes a relation between arteriosclerosis and nutrition, but the facts so far ascertained are highly suggestive.

Conclusion

It can be said that there is no particle of evidence which suggests that the vast majority of the population of this country are suffering from the effects of calcium insufficiency. Indeed, with a high degree of certainty it can be affirmed that the calcium intake under the present dietary regime is ample. On the other hand, a considerable amount of evidence exists that large sections of the population are in the habit of using too much of the type of food which is rich in calcium. There may be an indication for reducing the food calcium, but there is none at all for increasing it. Sir John Orr concedes that in half the population the calcium intake is satisfactory. Well, this half will be suffering from the effects of hypercalcaemia if the calcium content in our diet is raised.

We are indebted to Prof. Roaf for invaluable help and to Dr. Parrington, who is in charge of feeding experiments at the Institute, for the rabbit aortas referred to in the text.

A CASE OF CEREBRAL CHOLESTEATOMA

BY

I. R. S. GORDON, M.B.

The following case seems to be unusual enough to merit description.

Case Report

The patient, a man aged 36, was admitted to hospital in March, 1940, complaining of headaches, attacks of giddiness, and a right-sided hemiplegia. He was quite well until 1933, when he began to suffer from attacks of giddiness, after which he could hear and see objects but was unable to understand what was said to him. These attacks continued to occur more often until in 1936 they recurred about once a month, and were associated with frequent headaches, both frontal and temporal. At this time there were no visual defects or loss of consciousness, his blood pressure was 125/90, and no abnormal physical signs were found. His headaches were controlled by 10 grains of aspirin. His case was diagnosed as petit mal. In 1937 he was admitted to hospital with a left-sided mastoiditis. A mastoidectomy was performed. After this his condition showed a temporary improvement, but in 1939 he began to deteriorate, and developed clumsiness, with progressive weakness of the right side of the face, the right arm, and the right leg. There was no visual defect or vomiting.

Examination.—On admission the findings were: Constricted pupils, equal, but reacting only sluggishly to light and accommodation; lack of expression and weakness over the whole of the right side of the face; slight deafness in the left ear; power and co-ordination defective in the right arm and leg as compared with the left side; tendon jerks in the right arm and leg exaggerated; right abdominal reflexes absent; plantar reflexes extensor on the right, flexor on the left, side; temperature 97.6° F.; pulse 80; the optic disks were both normal; forced grasping not present; speech normal; mental state normal apart from a slightly defective memory and some lack of a sense of proportion.

Investigations.—On lumbar puncture C.S.F. fluid, clear, colourless, and without clot, was obtained under a pressure of 190 mm. of water; cells, two lymphocytes per c.mm.; albumin 30 mg., sugar 40 mg., and chlorides 710 mg. per 100 c.cm. A blood count showed 5,900,000 red cells per c.mm., 112% haemoglobin (Haldane), and 8,000 white cells; the blood sedimentation rate was within normal limits. The Wassermann test gave a doubtful result, and the Meinicke reaction was negative. A radiograph of the skull showed no evidence of neoplasm; but a special radiograph of the mastoid processes revealed sharply defined translucent areas replacing the left mastoid air cells, with an adjacent sclerosis, suggesting post-operative translucency or possibly cholesteatoma; the right side was normal. An electro-encephalogram disclosed abnormal delta waves, frequency 2½ to 3 per second, accentuated by overbreathing—indicative of a slowly growing space-occupying lesion (neoplasm, abscess, or granuloma) localized to the left temporal region.

Course.—On April 8 and again on April 12 the old mastoidectomy wound was explored, and fluid was obtained from beneath the dura—20 c.cm. on the first occasion and 90 c.cm. on the second. This fluid was pale yellow and translucent, with flaky shimmering crystals. It was reported by the pathologist to contain numerous epithelial scales and cholesterol crystals but no pus cells or micro-organisms, and was described as similar to that obtained from a branchial cyst. Three days later the patient developed a pyrexia of 103° F., headache, neck rigidity, and a positive Kernig's sign. The cerebrospinal fluid was now turbid with numerous polymorphs, and Type I meningococci were grown. In spite of sulphapyridine therapy his condition slowly deteriorated, and he died on April 22.

Post-mortem Examination.—A necropsy was performed, and besides evidence of a diffuse purulent leptomeningitis, a tumour 8 cm. in diameter was found. This appeared to replace the left temporal lobe and a large portion of the left frontal lobe, to form part of the wall of the left lateral ventricle, and to compress the right temporal and frontal lobes. It was soft and friable, and appeared to be encapsulated in some parts, though it was difficult to say macroscopically whether the tumour compressed or invaded the brain tissue.

Microscopical examination revealed that the soft inner portion of the tumour consisted mainly of squamous epithelial cells and cholesterol crystals. From sections of the edge of the tumour it was seen that the boundary was a thin layer of stratified squamous epithelium. The zone external to this consisted of compressed nervous tissue and showed a heavy fibrillary gliosis with some thickening of the walls of the blood vessels.

Commentary

There seems little doubt that this tumour was a cholesteatoma, the histological report agreeing well with previous descriptions of this type of tumour, especially in the presence of an external limiting zone of stratified squamous epithelium. Unusual features are the large size of the tumour and the late development and mild character of the clinical manifestations.

It is generally thought that cholesteatomata arise from embryonic cell inclusions of an ectodermal origin, possibly in connexion with the branchial clefts. Some authors, however, have suggested that they arise—especially those of the middle ear—by metaplasia of the columnar epithelium of that cavity secondary to chronic inflammation (Critchley and Ferguson, 1928). In the latter connexion it is perhaps of interest that in this case mastoiditis was present, and the clinical history would seem to indicate an early involvement of the inner ear.

The situation in which the tumour was found accounts for the relatively slight clinical manifestions, in spite of the size and extent of the growth. The histological examination seems to show that the brain was grossly compressed rather than invaded by the tumour. The left frontal and temporal lobes are silent areas, and it is characteristic of a tumour in this position that the first localizing sign should be a right hemiplegia and should appear so late after the onset of the patient's illness.

Acknowledgment must be paid to Prof. Golla and Dr. Grey Walters for the preparation of the encephalogram and to Dr. R. M. Norman for the preparation and examination of the tumour sections.

Skim-milk, perhaps because of a popular old advertisement, is a rather opprobrious term, and the prejudice against this product in America is such that according to the U.S. Department of Agriculture only about 12% of the skim-milk produced is used in the manufacture of dairy products. In a paper by Mr. J. S. Abbott at the sixty-ninth annual meeting of the American Public Health Association it was urged that the misuse of skim-milk constitutes an enormous economic waste. It contains all the essentials of whole milk except the milk fat and fat-soluble vitamins, and it even contains a certain amount of each of these, though not so much as whole milk. The Nutrition Committee of the League of Nations stated that, pint for pint, skim-milk contains more calcium, phosphorus, iron, and protein (though, of course, fewer calories) than whole milk, and is much cheaper. It is a good foodstuff for animals, but to feed it to pigs is unsound economics because it requires 10 pounds of the food nutrients in skim-milk to produce 1 pound of food nutrients in the form of pork. Industry and legislative effort to create a market for this wholesome foodstuff, says the author of the American paper, would be in the interest of consumers and dairy farmers alike, and there ought not to be any restrictions or discriminations against compounding skim-milk with other foodstuffs for use as human food in the manufacture of food products that supply a want of the people and that can be produced economically to advantage.

Clinical Memoranda

Benign Synovioma arising in a Bursa

The following case is rare enough to warrant publication.

CASE REPORT

A married woman aged 69 was admitted to St. Bartholomew's Hospital on March 3, 1939. Four years before admission she had fallen in the street and hurt her right knee. Fomentations were applied and she was confined to bed for six weeks. Six months later the medial side of her right knee had become swollen and inflamed, and what she described as a "wart" appeared in this situation. There was slight pain and the movements were only slightly impaired. At the Poplar Hospital the condition was diagnosed as an "infected wart with prepatellar bursitis." Fomentations were applied, and on one occasion the fluid was tapped, a few centimetres of blood-stained fluid being withdrawn. Haemolytic streptococci were grown from the fluid.

She attended the Poplar Hospital out-patient department for about three weeks. At this time the swelling had almost disappeared, but the "wart" remained. This slowly increased in size. After a while fluid reaccumulated, and the patient applied fomentations and kept the knee bandaged. She found that on applying pressure over the swelling fluid could be expressed through the "wart." If left for two or three days fluid would rapidly reaccumulate, resulting in a painful swelling in the centre of which the "wart" was situated. This swelling would go down on squeezing out the fluid.

On examination there was a fluctuating swelling about 3 in. by 2 in. situated over the medial condyle of the tibia medial to the tuberosity. It had the characteristics of a bursa, but did not correspond in position to any of the constant anatomical bursae. In the centre of the swelling there was an area about 7 mm. in diameter covered with a crust. On removing the crust a mass of closely packed papilliferous processes was seen, giving the surface a warty appearance. On pressing the swelling serous fluid exuded from this warty portion. All fluid was expressed easily. A solid mass could then be felt under the skin. Pressure on this caused the papilliferous processes to bulge through the skin opening. Movements of the right knee were full and painless. There was no abnormal mobility and no crepitation on movement. No patellar tap was obtained. The glands in the groin were not enlarged. The patient was quite well in herself, and general medical examination revealed nothing of note. There had been no loss of weight. The family and past histories contained nothing relevant.

A radiograph of the right knee showed marked osteophytic formation on the tibia, femur, and patella. There was little evidence of erosion of cartilage. A small lateral incision was made on each side of the central warty area. Pressure then delivered a mass of peculiar papilliferous growth through the incision. This was removed and kept for section. A quantity of the same type of tissue was left behind. It appeared to extend towards the knee-joint. The skin incision was closed with silk. The section was reported on by Dr. Magnus. He stated: "Section shows a tumour consisting of sheets of cells which in some areas resemble fibroblasts and in others reticulum cells. Mitotic figures are spare. The tumour should be regarded as a primary tumour of synovial membrane—a synovioma. These are tumours which vary greatly in their degree of malignancy. This tumour looks relatively benign and shows no evidence of rapid growth."

The tumour was excised by Mr. Hosford under general anaesthesia. An elliptical incision was made around the affected area of the knee with a wide margin of tissue. The affected area was dissected out, together with fatty surrounding tissue. The lump showed no communication with the knee-joint. It was found to lie entirely in the subcutaneous tissue and measure about 2 in. by 1 in. by 1·2 in. The wound was closed in layers. The report on tissue removed ran as follows: "The specimen consists of a piece of skin bearing a sinus opening leading to a cavity lined by proliferative tissue. There is no macroscopic evidence of invasion of the surrounding tissues. Section shows the bursa to be lined by a transitional type of epithelium which in many areas is proliferating and shows evidence of locally infiltrating the surrounding tissue. The tumour would appear to be a type of synovioma arising from a bursa."

Fifteen months after the operation the wound was well healed and there was no sign of local recurrence or of secondary deposits. The patient was in excellent health.

COMMENTARY

There are few reports of tumours arising from synovial membrane in the literature, especially of this country. These tumours have special histological features. Modern work inclines to the view that synovial tissue is a tissue *sui generis*, and it is not surprising, therefore, that it can give rise to tumours which, though in the past not well recognized, are nevertheless distinctive. Such growths have been found in relation to joints, tendon sheaths, and bursae. Most of the tumours reported as arising from synovial membrane have been malignant. A detailed description of the histology of these growths, together with a proposed classification for the whole group, will be found in the excellent paper by Berger (1938). It also contains an admirable review of the relevant literature.

On both clinical and histological grounds the tumour here reported was considered innocent, and the subsequent history supports this view. However, it is important to insist that a patient from whom any type of synovioma has been removed should attend at intervals for follow-up, because even in the case of highly malignant synoviomas a history of from one to seven years' slow local growth is often obtained before any signs of malignancy have set in. The lungs are the commonest site for metastases.

I have to thank Mr. Hosford for permission to publish this case.

R. N. HERSON, M.B., B.S.,
Assistant Medical Officer, Hemlington.

At the recent council meeting of King Edward's Hospital Fund for London the Duke of Kent read a special message from His Majesty the King expressing His Majesty's admiration for the way the hospitals were carrying on under the present difficult conditions. The Duke went on to announce that the King's Fund was about to make a Christmas distribution of £300,000 to the London voluntary hospitals, which brought the total amount distributed by the Fund since its foundation in 1897 to over £10,000,000. Twenty-two additional hospitals would benefit from this year's distribution, as the King's Fund area had been extended to cover the whole of the Metropolitan Police District. Referring to the opening last April of the Nursing Recruitment Centre, which is concerned with propaganda on behalf of nursing in voluntary hospitals, the Duke said he knew that hospitals could be relied upon to co-operate with the centre by keeping it informed of their needs. There were in London so many hospitals that girls who wished to take up nursing were apt to be bewildered. They might apply to hospitals with long waiting lists and become discouraged, while there might be others which would be very glad to accept them. The Duke concluded by expressing his sympathy with the hospitals throughout the country which had suffered so severely in the war. The large number of hospitals that had been seriously damaged, he said, and the heroism and devotion of the staffs in protecting and rescuing the patients had profoundly stirred public feeling. The hospitals were as much dependent to-day as ever before upon voluntary contributions for the maintenance of their ordinary work, and he had no doubt that many people would desire to express their sympathy by giving them increased support.

Reviews

TREATMENT IN GENERAL PRACTICE

Treatment in General Practice: Surgery (continued). Articles republished from the *British Medical Journal*. Volume IV. (Pp. 562; 143 illustrations. 16s. net.) London: H. K. Lewis and Co., Ltd. 1940.

This volume continues an important series of articles which have appeared in the *British Medical Journal* over a long period; three volumes have already been published. The present book contains fifty-five articles on surgical conditions as widely varied as fracture of the forearm and rectal prolapse, and each gives a brief but clear picture of an important subject; throughout the whole volume a uniformly high standard is maintained.

There is a wide field of surgery which is the domain of neither the specialist nor the general practitioner but in which success depends on skilful co-operation between the two. Hitherto it has been a somewhat neglected field, and the *Journal* has done a very sound piece of work in calling attention to its existence and to its importance, which, at the present time, when the full health of every individual is vital to our country, can scarcely be exaggerated. It is well that the surgeon should realize that the effective repair of a fractured finger may be of far more significance to the State than the brilliant removal of a carcinoma of the rectum, and that the general practitioner should realize how much may depend on his management of a simple injury.

In *Treatment in General Practice* we have a series of pen-pictures of the most modern methods of treating common injuries and disabilities. Each article represents the considered experience of an expert in a particular field, and may be taken as an authoritative statement of the latest practice. Even those of us who are in the closest contact with surgical work and surgical teaching can scarcely read a single chapter without finding some new point of real value. For instance, the account of supraspinatus tendinitis opens up an entirely new view of injuries around the shoulder-joint, while the article on the treatment of haemorrhoids shows that careful attention to exact detail which reveals the expert. But every article throughout the book shows exact practical knowledge, and no one who wishes to keep abreast of modern surgical technique can afford to be without it.

H. S. SOUTTAR.

SEX AND REPRODUCTIVE PHYSIOLOGY

Recent Advances in Sex and Reproductive Physiology. By J. M. Robson, M.D., D.Sc.Leeds, F.R.S.Ed. With an introduction by Prof. F. A. E. Crew, M.D., D.Sc., F.R.S. Second edition. (Pp. 329; 62 illustrations. 15s.) London: J. and A. Churchill, Ltd. 1940.

During the six years that have elapsed since the first edition of this book was published the research work of the chemist has added much to our knowledge of sex hormones. Pure crystalline substances have been isolated, their structure analysed, and active synthetic forms prepared. One of the immediate results of this has been a great increase in the amount of certain of these substances, especially the oestrogens, available for clinical trial, and their effects have been tested in a variety of conditions. It is difficult to keep pace with progress in endocrinology, and for this reason the second edition of Dr. Robson's book, with its carefully and clearly summarized account of the subject, will be welcomed. New chapters dealing with the properties of the androgens, the chemistry of the gonadotrophic hormones, and the technique of hormone standardization have been added. Those sections devoted to the therapeutic uses of the hormones summarize the results obtained by numerous workers, but fail to discriminate adequately between the claims of individuals and the results of a more general clinical experience. In the same sections the use of the terms "anovular haemorrhage" and "metropathia haemorrhagica" as synonyms is incorrect and is likely to cause confusion, but it should not be difficult to remedy these defects in subsequent editions.

The illustrations are good, and an excellent summary of relevant literature is given. The book can be warmly recommended.

THE ART OF SURGERY

The Art of Surgery. A Textbook for Students and Practitioners. By H. S. Souttar, D.M., M.Ch.Oxon., F.R.C.S. Fourth edition. (In two volumes, pp. 402 and 377. 25s. net the two volumes.) London: William Heinemann (Medical Books) Ltd. 1940.

The production of a fourth edition of Mr. Souttar's textbook in two handy-sized volumes, printed in a clear modern type, makes this the most attractive issue that has yet appeared, while the thorough revision which the text has undergone in order to bring it up to date should make a wide appeal to medical students everywhere. Useful little black-and-white sketches, many of which were placed in the wide margin of previous editions, are now incorporated in the text and are the better for this rearrangement. We have always thought the title a happy one, being reminded of a remark of Wilfred Trotter's that medicine (which may be held to include surgery) is an art rather than a science—the suspension of judgment so essential in science cannot for long be maintained by a practitioner who would retain the confidence of his patient. Many will not agree with Mr. Souttar that division of the sensory trigeminal root is an operation of considerable danger, as in trained hands the mortality of this procedure is less than 1%; nor that a permanent cure of trigeminal neuralgia is obtained from alcohol injection of the ganglion, because many cases relapse in from six months to two years after successful injection.

But on the whole we can find little to criticize in the text, and have to congratulate the author on its essential soundness throughout and on the great improvement he has been able to effect on previous editions. This work is a safe guide for the student beginning surgery and entering the surgical wards, and will probably replace some of the older many-times-revised textbooks, whose original authors have long since died and whose present text, in the hands of followers, they would probably not recognize. Students using this textbook will be wisely and soundly inducted into the art of surgery.

CLINICAL PATHOLOGY OF EYE DISEASE

Introduction to Ophthalmology. By Peter C. Kronfeld, M.D. (Pp. 331. $3.50 post paid; or 19s.) Springfield and Baltimore: Charles C. Thomas; London: Baillière, Tindall and Cox. 1940.

Prof. C. Kronfeld's work, though intended for students, is not an elementary textbook but an attempt to formulate the principles of "that portion of ophthalmology which is a necessary part of basic medical education." The book is presented as a supplement to the short clinical course in ophthalmology that students have to undergo; it stresses pathogenesis and omits altogether details of diagnosis and treatment except in so far as they illustrate a general principle. Many common diseases find no place in this volume, as "they are unimportant for the exposition of ophthalmological principles." Within the

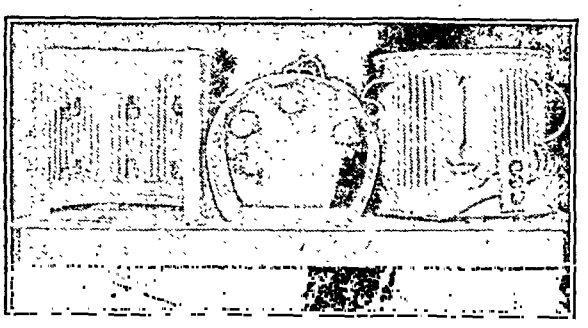
strict limits the author has imposed upon himself he has produced a readable and useful series of essays of interest to the specialist rather than to the student. Prof. Kronfeld has drawn widely on the basic sciences in his interpretation of such ophthalmological problems as cataract and glaucoma, and has ably summarized much recent work on anatomy and physiology in his chapters on the visual pathways and on the retinal circulation. With so much that is new and provocative it is a pity that the uniformity of the book is marred by digressions into elementary expositions and by some looseness in style. This work is really an attempt—the first of its kind—to produce a textbook on the clinical pathology of eye diseases, and it is regrettable that the author had not more clearly delineated the scope of his efforts and so avoided the pitfall of attempting to serve conflicting objectives. Incidentally, are English social titles so confusing that Sir Jonathan Hutchinson has to be recognized under the appellation of Sir Hutchinson? In spite of its defects the book is well worth perusal by ophthalmologists interested in the scientific aspects of their specialty.

Notes on Books

The association of tuberculosis, such a commonly chronic disease, with literary distinction and that rare gift, genius, has aroused a considerable amount of interest. It may be recalled that the late Sir Henry Head, in the Goulstonian Lectures in 1901 on "Certain Mental Changes that accompany Visceral Disease," dealt with this association and utilized his observations when house-physician at the Victoria Park (now the London) Chest Hospital. Dr. L. J. Moorman of the Oklahoma University School of Medicine, medical director of a private sanatorium for a quarter of a century and much interested in psychopathology, has in *Tuberculosis and Genius* (Cambridge University Press, 15s. net) now brought out an attractive volume on this subject. In an introduction he reviews the opinions of others, especially concerning the hypothetical stimulating action of a tuberculous poison on the brain, which may bring out a latent streak of genius. There may, however, be other mechanisms: for instance, the recognition that illness is a handicap and that life is shortened, which—art being long and time fleeting—induces a powerful compensatory effort at achievement. A list, admittedly incomplete, is given of more than eighty distinguished writers who were tuberculous, beginning with John Milton and including Samuel Johnson, who in early life was touched by Queen Anne for tuberculous glands in the neck. The remainder, and the greater part, of the book is devoted to ten separate analytical essays, each with a portrait—on Robert Louis Stevenson, Friedrich Schiller, Marie Bashkirtseff, Katherine Mansfield, Voltaire, Molière, Francis Thompson, P. B. Shelley, John Keats, and St. Francis of Assisi—with the object of showing the more evasive elements of personality as influenced by psychopathology, and how they become more tangible through the intimate presence of a chronic disease.

It is good to see that the war has not prevented the Medical Society of Individual Psychology from issuing its helpful pamphlets—helpful because they provide the general reader with straightforward accounts of medico-psychological problems that arise in the course of his daily practice. Pamphlet No. 22 (The C. W. Daniel Company, Ltd., 2s. 6d.) within forty-eight pages includes articles by Dr. A. Sandison, on escape and activities; Dr. R. Hargreaves, on the flight into normality; and Dr. H. Crichton-Miller, on discipline and leadership. The last article is by Dr. F. Marjory Edwards, on China under war conditions.

The appearance of a third edition of Dr. W. WILSON INGRAM'S small but comprehensive book, *The Diagnosis and Treatment of Diabetes* (Sydney and London: Angus and Robertson Ltd., 6s. 6d.) shows that it has established its usefulness in Australia. It is clearly and well written for the practitioner, who must find its clear directions, especially on diets, a relief in their dogmatism. The short new chapter on protamine-insulin treatment (the author calls it "modified" insulin) is the best in the book, and gives the practitioner real help by describing the significance of urine tests for sugar. The same is unfortunately not done with "unmodified" insulin, and this chapter contains only vague phrases about keeping the blood sugar normal. Surely, too, the reader—at least the English one—would find it easier if the terms "soluble" or "ordinary" insulin and protamine-insulin were used instead of "unmodified" and "modified" insulin. In the production of insulin all forms are modified from the pancreas elaborations and are liable to further modification as research produces new products. Such criticisms are minor, and the book is on the whole most helpful. The section on diagnosis, however, is confusing and should be rewritten. The blood-sugar curve on page 28 is described as mildly diabetic or else a lag-storage curve. It is typical of neither, and is so unusual that it is probably due to a technical error such as arises occasionally with the Maclean blood-sugar method, which the author recommends to practitioners.



Preparations and Appliances

A CHEAP RADIANT-HEAT CAGE

Dr. CHARLES MOFFATT (medical officer in charge, first-aid post, Irlam, Manchester) writes:

The following description and photograph of a radiant-heat cage suitable for the treatment of cases of shock at first-aid posts may be of interest to medical officers and others in charge of such posts and of hospitals where the treatment of cases of shock have to be undertaken and where provision of a cheap cage would be appreciated.

Irlam is a semi-rural district which has no hospital. As a consequence our first-aid post had to be equipped with more than the bare necessities allowed by the Ministry, consisting of dressings, stretchers, a few instruments, and drugs. All other equipment deemed necessary had to be bought or improvised. The cage was made from a galvanized dustbin: the bottom was removed and the body of the bin opened down its seam; the sharp edges were padded with wool, kept in position by strips of elastoplast. To hold the lamps six

small wall brackets made of bakelite and bought from Woolworth's were fitted, three switches were also bought at Woolworth's, fixed to a wooden block, and fitted to the outside of the cage. The wiring of the switches, brackets, and plug was effected by using twin flex cable running through lengths of flexible gas-tubing: this was done to prevent fraying of the cable by blankets and rugs which would be thrown over the cage when used. The lights are wired in pairs, and can therefore be switched on in pairs, so that the amount of heat generated can be regulated. A three-core flex cable is used to connect up to the power plug; this carries the earth from the metal parts of the cage. The temperature can be checked by using an ordinary bath thermometer. As this cage is being employed for heating purposes and not for the treatment of fibrositic conditions, six 150-watt tungsten lamps are used instead of the carbon filament lamps usually fitted in a radiant-heat cage.

The post was fortunate in having as one of its members a plumber, who made the apparatus in a few hours at a cost of 35s. Should anyone wish for further particulars I shall be glad to supply them if the inquirer will write to me.

BRITISH MEDICAL JOURNAL

LONDON

SATURDAY JANUARY 11 1941

THE TREATMENT OF CANCER

"Watchman, what of the night?" These were the words used by Sir Alfred Pearce Gould in his Bradshaw Lecture in 1910 when surveying the cancer problem. Now another Middlesex man, Sir Alfred Webb-Johnson, in his Bradshaw Lecture on "Pride and Prejudice in the Treatment of Cancer," published in last week's and the current issue of the *Journal*, bids us take heed of the watchman's answer: "The morning cometh, and also the night: if ye will enquire, enquire ye. . . ." Sir Alfred Webb-Johnson now gives us the answer to his inquiry into the problem of the treatment of cancer. It is an answer which is at once balanced, critical, and stimulating, and one which should give encouragement and hope both to the medical profession and to the victims of cancer. The treatment of malignant disease is dynamic and not static, but its evolutionary aspects tend to be obscured by day-to-day problems. Improvements in treatment are only possible when the results of long-term research can be reviewed and assessed. The latter part of the nineteenth century was the age of heroic surgery in the treatment of malignant disease, and of operations which are now often dismissed lightly as "mutilating." The first two decades of the present century saw the introduction of radiotherapy and the opening up of new and novel lines of treatment. During the two decades from 1920 to 1940 there has been a great extension of radiotherapy, and intensive study of its results, successes, failures, and mistakes, the introduction of systematic case-recording for research purposes, and, finally, the passing of the Cancer Act, with its provision for the setting up of regional centres for the treatment of malignant disease. The past two decades have also seen a great improvement in our knowledge of the natural history of malignant disease, of its pathological features, especially in relation to the histological method of grading tumours, and the introduction of newer diagnostic methods. All these advances have made for much greater scientific accuracy, and with it the clinical dogmatism of the Victorian surgeon has gradually disappeared. Meanwhile we have to face the everyday problem of the patient with malignant disease who requires urgent treatment. He or she must have the best that we can offer, yet the results of what we do to-day can only be fully evaluated in the course of five or ten years. The immediate problem and the long-term research are but the obverse and the reverse of the problem of the treatment of malignant disease. The present war, with its disorganization of population and hospitals, is an opportune moment to survey the results of the labours of the past twenty years.

But why "Pride and Prejudice in the Treatment of Cancer"? Here is Sir Alfred Webb-Johnson's answer: "When I embarked upon my inquiry I found an undercurrent of talk—wild uninformed criticism, a tendency to exaggeration of failures and overstatement of successes. Surgeons and radiotherapists were often in disagreement. There was indeed an atmosphere of 'pride and prejudice.' . . ." The surgeon, knowing he could obtain certain results by operation, was not always interested in radiotherapy. The radiotherapist was often blind to the possibilities of surgery. All of us in this country were too parochial in our outlook, and too inclined to ignore or to dismiss the work of the man across the way, while turning to Vienna, Paris, New York, or Milwaukee as the true Mecca. But this challenge to surgery from radiotherapy has been accepted, and has proved an immense stimulus to the study of the treatment of malignant disease. During the past twenty years the practice of radiotherapy has grown and is still growing at a remarkable rate. Many mistakes have been made in the sphere of radiotherapy, many of the cancer statistics are useless for the purposes of scientific comparison, and methods of treatment are still far from uniform. "In fact, in a recent report of the Radium Commission it is stated that 110 different combinations had been distinguished for the tongue, 53 for the floor of the mouth, 86 for the breast, 56 for the lip, and 66 for the uterine cavity"—truly a bewildering variety.

In a recent paper Paterson[1] dealt very fully with the Ministry of Health publication by Sholto Mackenzie on "Cancer: An Inquiry into the Extent to which Patients receive Treatment." This report divided cases into three groups on the basis of the actual treatment they received. The first, or "curable," group (or potentially so) included the uterus, skin, breast, and buccal cavity; the second, or "treatable," group the stomach, intestine, prostate, rectum, bladder, ovary, larynx, and miscellaneous; the third, or untreatable, group the liver, pancreas, lung and bronchus, gall-bladder, mediastinum, and oesophagus. In the first group the percentage of treated cases varied from 56% to 71%, in the second group from 5% to 42%, and in the third group from 0% to 21%. Treatment is thus likely to be carried out most often if the malignant process is in the uterus, including body, cervix, and vagina; the skin, including genitalia; the breast; or the buccal cavity.

In his survey Sir Alfred compares the results of surgery with those of radiotherapy under the conditions which justify such a comparison. In the case of the skin, although radiotherapy will cure a large proportion of cases, surgical excision is still the method of choice if disfigurement and mutilation can be avoided. The results of radiotherapy in the treatment of cancer of the lip are as good as or better than those of surgery, and these are often achieved without loss of substance. In the case of the tongue the results of radiotherapy closely approximate to those obtained by Butlin, but in view of the mutilation and disability resulting from extensive operations radiotherapy is considered the method of choice for dealing with the primary lesion. The results of the treatment of intrinsic cancer of the larynx by laryngofissure and by irradiation are identical, though only a small group treated by the Finzi-

[1] *British Medical Journal*, 1939, 2, 904.

Harmer technique are available for study. Malignant disease of the oesophagus is still a problem to both surgeons and radiotherapists, and although surgery can claim a few brilliant successes, there have been as yet no lasting cures in cases treated by irradiation. In the case of rectal carcinoma Miles was able to obtain a five-year cure rate of 83% in Stage A cases, but Gordon-Watson has shown that the results of radiotherapy were too uncertain to justify its use in operable cases. In the case of carcinoma of the cervix the results of irradiation are better than those of surgery, even of so experienced a surgeon as Bonney, whose results are not likely to be surpassed. For this reason radiotherapy, with the greater uniformity in its application, is likely to be of much greater value than mass surgery. Finally, in the case of cancer of the breast the comparison of the results of surgery and of radiotherapy is difficult. Gordon-Taylor has obtained a ten-year survival rate, in 84% of Stage I cases, but although Keynes and others have made many valuable contributions to technique, the absence of pathological data makes comparison of results difficult.

It is thus apparent that about half the patients suffering from cancer need some form of radiation therapy, that this work can only be undertaken under the most favourable institutional conditions, and that intensive research is required on every aspect of the cancer problem. At present only about a quarter of the cancer sufferers in this country receive the skilled attention they need and deserve. During the past twenty years the treatment of cancer has made real progress, but much still remains to be done. Radiotherapy has established itself as a valuable method, and the problem of cancer treatment must be viewed as a radio-surgical one. But radiotherapy also has other advantages. It offers to the fear-ridden patient an alternative to the knife, it offers a line of treatment in cases in which operation is contraindicated, and it offers the possibility of greater uniformity in application. Much will depend on the working out of the details of the Cancer Act, but whatever is done treatment and research must go hand in hand. In his review Sir Alfred has given great encouragement to the profession and to the victims of cancer, but he has also pointed out that, as in so many other spheres of medicine, adequate planning is essential if the best results are to be obtained. It is also suggested that there is a shortage of trained personnel, particularly of radiotherapists, for carrying out the proposed treatment at regional Cancer Centres. This may be true; but it is equally true that in this country there are hundreds of highly qualified men who could undergo the necessary training and carry the lamp of knowledge and research to all parts of the country. Before, however, the work and services of these men are made available to the community much "pride and prejudice" in hospital control, administration, and outlook must be broken down. There will be no lack of willing or able volunteers for "planned" medicine when it offers first-class facilities coupled with opportunities for research. One of the few wise remarks ever made by Gideon Harvey, physician to Charles II, comes to mind: "How few good surgeons there are to be found, may easily be judged by what is premised; yet it is very probable, there are more in England, than elsewhere."

HOSPITAL ADMINISTRATION IN THE LONDON COUNTY COUNCIL

It is now fifteen years since the Royal Commission on Lunacy and Mental Disorder reported. The tenor of its recommendations was that the lunacy code should be relaxed with a view to such approximation of the treatment of mental disorder to the treatment of physical ailments as may be consistent with the special safeguards indispensable when the liberty of the subject is infringed. In the new era of enlightenment of which the Royal Commission itself was a sign and a fulfilment the partition existing, both in the public mind and in administration, between physical and mental illness has grown thin. This is evidenced by the establishment of out-patient departments for mental diseases in general hospitals, the new understanding of the mental basis of many cases of physical disorder, and in other ways. The very change in terminology whereby the words "asylum" and "lunatic" have given place to "mental hospital" and "person of unsound mind" is in line with the increasingly humane and scientific care of the insane which has characterized the last century and especially the last twenty-five years.

There still remain, however, some things to be done, or some relics to be cleared away, before administrative procedure, which always lags behind public sentiment, can be said to reflect the new spirit as fully as it might do. Even under the London County Council, the largest and most progressive of hospital authorities, the mental hospitals are administered by a department separate from that of the medical officer of health. The reason for this is easily given. Three years after the report of the Commission presided over by Lord Macmillan, the Local Government Act of 1929 was passed, itself the result of an earlier Royal Commission which had reported first in 1925 and again in 1928. In London the passage of that Act was followed by the largest transference and co-ordination of hospitals in history. The whole of the services of the extinct boards of guardians and the powers and duties of the Metropolitan Asylums Board devolved upon the London County Council, whose medical staff, with Dr. (now Sir) Frederick Menzies at its head, had the task of adapting the large number of general and special hospitals which had been taken over and of bringing them up to the required standard. This was of its kind the largest health measure that any local authority had ever shouldered, and it was the magnitude of the task which caused the postponement of one other rather obvious piece of reconstruction whereby the mental hospitals and the institutions for mental defectives, now accommodating nearly 34,000 patients, would have come under the same administrative direction.

In the London County Council, therefore, there are two quite different departments both dealing with hospitals—one of them directed by the Hospitals and Medical Services Committee, with the medical officer of health as executive officer, and the other by the Mental Hospitals Committee, with its own administrative head. At the time of the transference, eleven years ago, there was much debate whether all the hospitals, including the mental hospitals, should not be grouped together in the one department, in harmony with the report of the Royal Commission on Lunacy; but it

was decided, after careful consideration, to reserve such incorporation until the immense amount of work involved in the transference had been completed, and the general and special hospitals had been thoroughly reorganized and built up into the first-class service that they now represent, an example to the entire municipal world. The burden of the task which the Act of 1929 placed upon the medical officer of health and his assistants was considered to be quite enough for the time being, but it was always understood that incorporation was only deferred, not abandoned. A special report was adopted by the Council at that time which, *inter alia*, charged the Mental Hospitals Committee with the exercise of the transferred functions relating to the care of persons suffering from mental infirmity or defect, but indicated that a clear dividing line between this field and that allocated to the Central Public Health Committee (now the Hospitals and Medical Services Committee) could not be drawn, and that the two would have to act in close co-operation. As time has proved, and as was only to be expected in view of the character of our local government service, the existence of two separate departments has not proved to be any serious detriment to the communal health which they both served. Mutual courtesy and regard for administrative convenience have compensated, so far as they could, for an intrinsic anomaly. The same is true, no doubt, in the sphere of national administration of the relations of the Ministry of Health and the Board of Control. At the same time goodwill cannot always be depended on, in county halls any more than elsewhere, and, even if it could, its existence is no excuse for perpetuating such an arrangement. It is felt by many who are interested in the government of London that the time is ripe for such an incorporation, and the recent retirement under the age limit of the chief officer of the Mental Hospitals Department, Mr. R. H. Curtis, after a long period of devoted service, offers the opportunity of merging the two departments into an administrative whole.

The advantages of fusion are obvious. It is as strange to have within the same authority two separate departments dealing with health, with separate officials, responsible to separate committees, and issuing separate reports, as it would be, say, in the sphere of education to have one department dealing with drill and games and an unrelated department dealing with book learning, or to have a fire brigade which attended all fires except those due to gas explosions, these being dealt with by another brigade quite separately officered. This desire for merging is no question of mere bigness for its own sake or the aggrandisement of officials. It is a question, first of all, of efficiency, of the pursuit of a consistent policy, of the ability to plan in a large way. Such a reform might avert delay in many cases, might promote economy in the purchase of equipment and supplies and prevent overlapping, and might even facilitate interchanges of staff between general and special hospitals on the one hand and mental hospitals on the other, to the advantage of the officers concerned. Whether the institutions are dealing with physical or with mental illness much the same abilities are required in the committees which shape policy and the staff who carry out instructions, except, of course, that in mental hospital work there are certain special considerations, legal and other, for which provision must always be made.

The London County Council now has the opportunity of making a departure which would not only facilitate its own internal work but would be an example to local authorities generally, and in line with —in a sense the completion of—the metamorphosis, which began a century ago, of asylums for detention into hospitals for treatment.

TOWARDS SOLVING THE SHELTER PROBLEM

It was announced last week that the Government has decided to make important administrative changes in connexion with the control of air-raid shelters. The Ministry of Home Security will remain responsible for the number, location, and construction of shelters, and the Ministry of Health for their management and for all matters concerning the health and comfort of those who use them. No doubt the Ministry of Home Security will take the advice of the medical staff of the Ministry of Health on such aspects of shelter construction as bear directly upon hygienic conditions. While policy will be directed by the two Ministries within their clearly defined spheres, administrative responsibility will devolve on Regional Commissioners, who, acting through local authorities, will be responsible for all matters relating to the construction and management of shelters. Alderman Charles W. Key, M.P., who set such a fine example in organizing civil defence in his own borough of Poplar, has been appointed Regional Commissioner for the London Civil Defence Region. In addition to the existing regional staff he will also have the help of seventeen other officers of the Ministry of Health. He proposes to appoint some well-qualified woman who will give her whole time to the study of the problems that affect women and children. The Ministry of Food will continue to be responsible for the supply of food to the canteens.

During the past weeks we have published in the *Journal* a survey of conditions in London shelters, and have noted how far the recommendations of Lord Horder's Committee have been carried out. The multiplicity of authorities and the existing disparity between the actions of local authorities led us to put forward a plea in the *Journals* of December 7 and 21 for unification of shelter control. The necessity for some such action was emphasized by the *Times* in its leading article of December 27, in which it was stated, "Central authority and responsibility ought to be concentrated in a single department endowed with the necessary powers and able to take and execute decisions with promptitude." The shelter problem is neither a local one to London nor a temporary one, and we may have to face another winter of war in which the cities of this country will be subjected to even more intense bombardment than they already experience. Although Ministerial responsibility in relation to shelters has been clearly defined and administrative action now lies in the hands of Regional Commissioners, vigilance will still be necessary and watch must be maintained against the dangers of complacency. Apart from measures to be taken against the risk of infection, the prime need is for the

establishment of reasonable hygienic conditions of living in the shelters. When these have been secured, not in some shelters but in all, an imaginative effort will be required to seize some good out of the evil predicament forced upon us by aerial bombardment. The shelter population, which needs must be drawn from the poorest sections of the community, may be taught those elements of hygiene which they neglect in times of peace, and be educated in measures of preventive medicine. One good alone is already being secured—namely, the widespread immunization of children against diphtheria, to which desirable end the Ministry of Health has given an energetic drive. The Central Council for Health Education, at the invitation of the Ministry, now has ready for distribution a health booklet for shelterers and a series of leaflets dealing with special problems. These have been written in simple direct language, and if there is sufficient indication that they are not without effect, then no doubt the Central Council will continue the work of educating the shelter population. Food has to be measured in terms of guns, ammunition, tanks, and planes, and the Ministry of Food will no doubt carry into the shelters the excellent work it has begun, through the medium of advertisements in the daily press and in other ways, in instructing the people what to eat.

In this small field alone—for only a small proportion of the population lives in the public shelters—the seeds of post-war reconstruction may be sown here and now.

BLOOD CHANGES IN VITRO

The storage of blood for transfusion has focused attention on the changes which occur in red cells surviving outside the body. Recent papers from the Army and the Medical Research Council Blood Transfusion Services[1 2] show that the majority of the erythrocytes remain viable for the purpose of transfusion for at least a fortnight after withdrawal from the donor, and that their chances of survival are improved by the addition of glucose to the citrate solution used as anticoagulant. Every clinical pathologist is now familiar with the morbid anatomical changes which occur in the red cells on storage. The cells become more spherical, with a diminished resistance to haemolysis by hypotonic saline, a decreased tendency to form rouleaux, and a consequent slowing in the speed of sedimentation. The war has made haemolysis and the pre-haemolytic changes in the red cells a matter of common interest, but they have been for many years the subject of intensive research, because they touch on some of the fundamental problems of physical chemistry and pathological physiology. The world of lyospheres and electrokinetic potentials in which these problems are discussed must remain closed to the general medical reader, though it is there that he must look for the final solution of these problems. More easily understood is a paper by Furchgott[3] on the transformation of mammalian red cells from disks to spheres, which occurs when a saline suspension of the cells is placed between a glass slide and cover-glass. This change is in part due to the alkalinity of the glass, but there is also evidence that the glass adsorbs out from the suspension a protein which protects the cells from sphering. This protective anti-sphering factor is contained by both serum and cells. Fahraeus,[4] on the other hand, has shown that when the erythrocytes and plasma are kept separate from each other, as after sedimentation, the haemolytic agent lysolecithin is formed in the plasma. The development of lysolecithin and the pre-haemolytic changes which are associated with its presence do not occur in life owing to the constant interaction at the erythrocyte-plasma interface, which maintains the two moieties of the blood in good health. Lysolecithin was first discovered in the study of the haemolytic action of snake venom, in which it is the all-important intermediary. Singer[5] has followed up the ideas of Fahraeus, and has prepared lysolecithin from normal animal or human serum, to use it as a means of testing red-cell fragility. The resistance of various types of erythrocytes to lysolecithin and to hypotonic salt solution does not by any means run parallel, and there appears to be an important difference between the spherocytes of congenital haemolytic jaundice, which are much less resistant to lysolecithin than normal red cells, and the spherocytes of various acquired and symptomatic types of haemolytic icterus, in which the lysolecithin fragility is normal although the saline fragility is altered. It would be interesting to see how far these ideas of Furchgott, Fahraeus, and Singer are applicable to the solution of the problems involved in the storage of blood for transfusion.

ADIE'S SYNDROME

The considerable literature that has grown up on the myotonic pupil since Adie, in an article in these columns ten years ago,[6] clearly brought out its association with loss of tendon reflexes has done much to clarify the clinical picture and but little to reveal the anatomical basis of the affection. It is now accepted that the light reflex is not absent but sluggish in the myotonic pupil, often not being revealed until the patient has first been kept in a dark room for a few minutes. In 80% of cases the pupillary disturbance is unilateral; the reaction to convergence, though more brisk than to light, is slow and, like the light reaction, is followed by slow dilatation of the pupil; and accommodation may be affected. In all this there is a marked contrast with the Argyll Robertson pupil, from which it also differs in occurring more often in women (80% of the patients are women), in being seen most frequently in the age group 20 to 30 years, and in responding normally to atropine. The associated loss of tendon reflexes is not always present or may be the only sign of what must be regarded as a systemic infection, as the pupillary changes may be absent. That Adie's syndrome may be a familial affection is seen from the cases observed by Dressler[7] which occurred in three sisters, while the fact that it has been reported in a variety of neurological affections has rather tended to confuse the clear-cut picture of an innocent lesion which Adie sought to establish. In recording six new cases of the syndrome Scheie[8] points out that in all of them one pupil became markedly constricted on the instillation of 2.5% solution of mecholyl, a stable choline substance (acetylbetamecholine chloride); fifty normal controls gave no such response. Drawing on the work of Loewi, Dale, and others on the chemical mechanism of the transmission of a nerve impulse from the nerve ending to the effector cell, and on the phenomenon of sensitization of effector cells when the nerve supply is interrupted on the post-ganglionic route, Scheie holds that the pupillary changes in Adie's syndrome are to be explained by a partial parasympathetic denerva-

PRISONERS OF WAR IN BELGIUM AND OCCUPIED FRANCE

REPORT OF INTERNATIONAL RED CROSS DELEGATES

The International Red Cross at Geneva has appointed delegates to Germany and the territories it is occupying, also to Great Britain, Canada, Egypt, Greece, Italy, unoccupied France, and Kenya, to see that the terms of the international conventions are obeyed, to inspect prisoners of war and interned civilians in camps, and to act as liaison officers between the belligerent countries and Geneva. A representative has also been sent to Lisbon to supervise the passage of food parcels and clothing to prisoners of war. All the delegates are Swiss.

It is hoped shortly to receive explicit information regarding the health and dietary in the prison camps in Germany itself. The great difficulty is the extraordinary delay in communication with Geneva, amounting in some cases to six weeks. Meanwhile reports are to hand from the delegates to occupied France and Belgium, Dr. Marcel Junod and Dr. R. Marti. The reports from which we make the following extracts have been received by the British Red Cross and St. John War Organization in London from the International Red Cross. It appears that the treatment of prisoners—of airmen particularly—is satisfactory, all things considered, and that the British wounded in many cases are looked after by British doctors.

Dr. Junod was the first foreign representative to visit the several hospitals in Belgium and France where British wounded have been taken. At the Institut Bordet in Brussels he found seventeen private soldiers—all cases of open fracture, with osteitis and osteomyelitis—and reports that the treatment, under German specialists, was excellent and the food good, being the same as that of wounded Germans in the hospital. At the Hôpital Malines were seventy non-commissioned officers slightly wounded and three badly wounded. They were being cared for by two British doctors (Major Ralph Walter Ganderson [?Ralph Waldo Gunderson] and Major Donaldson Norman Stuart [?William Norman Stuart Donaldson]. Here again the medical care and the food were good. At the Military Hospital, No. 60, Ghent, there were 200 slightly wounded, twenty-nine more seriously, and seven not able to be moved; two British doctors were in charge (Major J. C. Steel) [?G. C. Steel] and Major H. R. Fosbery. Treatment was reported good and food sufficient. On their recovery and dispatch to German camps the men receive from the Belgian Red Cross a double set of underclothing. At the English Hospital in Enghien in Belgium there were 450 wounded, twenty-nine seriously. Here there was a large R.A.M.C. personnel—twenty-four officers, twenty-three non-commissioned officers, and eighty-three privates belonging to the Field Ambulance General Hospital 17/21. It is mentioned that the R.A.M.C. officers receive pay. The daily ration includes about 8½ oz. of bread, nearly 2 oz. of meat, and the same quantity of fats.

At two Paris hospitals, Hôpital Valdegrace and Hôpital Bejin, there were eighteen and fifty wounded respectively, and care, food, and treatment were good. At the Hôpital Ernemont at Rouen there were 123 wounded, of whom sixty were officers; fifty-nine were badly wounded. There were five British doctors at this hospital, the chief of whom was Major W. L. Kinnear, and twenty-four male nurses. Here again there was a good report as to care, food, and treatment.

The civil internment camp at St. Denis was also visited by Dr. Junod. Here 1,611 civilians were found in satisfactory living conditions. The morning ration included 1/2 oz. coffee and 1¼ oz. sugar; midday, vegetable soup and nearly 2 oz. meat; in the evening, coffee or sometimes tea, cheese, sausage, and about 2 oz. marmalade or 1 oz. butter. The Swiss Red Cross has sent a consignment of condensed milk for the aged and sick. There are seven British doctors and dentists in the camp, and there is a good hospital. Health and sanitation are satisfactory, and the equipment includes shower baths. The chief need of both the wounded and the interned seems to be soap.

Dr. Junod's assistant, Dr. Marti, has visited a number of camps for airmen prisoners. It is not certain where these camps are located, possibly in Germany itself. One of them consists of three wooden barracks, comfortable, heated, and protected against fire. The food is good, and the canteen sells fresh vegetables. The sanitation includes provision for hot showers, and there is plenty of space for exercise. In this camp there are 231 non-commissioned officers and fifty-seven privates. In another camp, where there are 126 officers and fourteen other ranks, the barracks are similar to the first, with comfortable rooms for two or four men. It is said that there are no complaints regarding food, and there is a well-stocked canteen. One hospital with a German doctor is shared by both these camps. At the time of inspection there were three airmen prisoners slightly ill. There had been no deaths.

Another camp for airmen, accommodating rather smaller numbers, consists of three large heated barracks, with rooms having one to three beds, and hot and cold water running. The food is good, similar to that of German officers at the camp, and there is a well-stocked canteen. In the hospital here there are twenty-three airmen, all nearly recovered except one badly burned and one wounded by bullet. One camp is divided into *Oberlager* and *Unterlager*, the former accommodating forty-four naval and forty-six army officers, with twenty-two other ranks, and the latter eighteen staff officers, 131 field officers, seventeen doctors, and forty-four other ranks. The food here is said to be plentiful and well chosen, giving 3,700 calories per day. Five officers wounded by bullets will be repatriated when possible.

INDIAN MEDICAL SERVICE

Recruitment of Emergency Commissioned Officers

In view of the expansion of the Indian Army the Government of India wish to recruit a considerable number of doctors in the United Kingdom for service as Emergency Commissioned officers in the Indian Medical Service for the duration of the war. The conditions of service of such officers have recently been revised, and the Government of India are now prepared to accept doctors up to 45 years of age for war service subject to their being considered suitable and physically fit for service in tropical countries. Emergency Commissioned Officers of the Indian Medical Service will be eligible for acting and temporary promotion above the rank of lieutenant appropriate to the duties which they are called upon to discharge, in the same way as officers of the R.A.M.C. Officers with specialist qualifications who are appointed to specialist posts will thus be eligible for acting rank appropriate to their duties. Pay will be at the same rates as for officers of the Indian Medical Service in peacetime, and passages to India at Government expense will be provided for officers but not for their families. Candidates will be required to attend at the India Office for interview and medical examination before being finally accepted for appointment. Those interested in the Indian Medical Service should address any inquiries to the Medical Adviser, India Office, S.W.1.

GAS DECONTAMINATION AT FIRST-AID POST

The Ministry of Health considers that the arrangements at many first-aid posts for the decontamination of gas casualties are inadequate and will be ineffective in action. Local authorities are therefore asked in a recent memorandum to review at once the facilities they have provided for this purpose. *A plan, with details of the lay-out, of a model* cleansing unit at a first-aid post accompanies the memorandum, and any new unit which it may be necessary to erect should conform to this model. Existing first-aid posts should be adapted so far as possible to provide the essential features of the model, which are as follows. Each unit should have four compartments: (1) an outside stripping shed, which should, of course, be above ground; (2) an inside undressing room; (3) a washing or shower room; (4) a dressing room. The object is to prevent the spread of gas vapour from the stripping shed onwards; the four compartments should therefore be sealed off from one another, and intercommunication effected through doorways covered with blankets, which should be wet when in use. Each compartment should have cross-ventilation. The memorandum concludes by pointing out that concentrations of gas may occur near first-aid posts, and that unless other suitable measures have been taken blankets should be placed in position on fixtures over all outer doorways, to be lowered immediately when necessary.

Correspondence

Medical Planning Commission

SIR,—The British Medical Association has indeed given its members a fine New Year's gift in announcing the formation of this body. It pleases me not only because it is our natural contribution to the national effort to show that "Britain carries on," but because it is an unmistakable sign that our Association is very much alive. A body which, while immersed in war work and with its working members and staff heavily strained, can plan for the future on this scale has every right to be proud of itself. This is the kind of initiative that we have a right to expect from the body which represents every class of our profession as no other body does. We shall follow the work of the Commission with great interest and the assurance that its composition guarantees zeal, competence, and comprehensiveness.

One point in your announcement particularly interests me—that is, the assurance that the visions and aspirations of the younger men and women will not be overlooked. I am the last man to undervalue experience, but there is always a risk that the minds of the older men, particularly when habitually immersed in medical politics, will become *polarized*. It is not easy for such men to get away from the ideas and technique of our "Proposals for a National Medical Service." But it must be done. The world has moved fast and far since these proposals were formulated. The Association has had a good deal of criticism from certain quarters, not altogether unmerited, for its lack of initiative in dealing with the shelter question and the Ministries in charge of it. I hope that this will receive the attention of the Commission and perhaps stimulate it to make an *interim report on how to deal with a* problem which is certainly a "wartime development" and which may have marked effects on "the country's medical services." Our Association has tackled many big things in its time. It never had anything more worthy of its steel than this.—I am, etc.,

Henley-on-Thames, Jan. 5. ALFRED COX.

R.M.B.F. *Christmas Gifts*

SIR,—It is with great pleasure that I inform you that we distributed £1,032 in Christmas gifts this year. This means a monetary gift to all our regular beneficiaries—deeply appreciated and valued by each one of them.

Will you please accept my warmest thanks for the help you gave in publishing my appeal and convey to your readers my sincere gratitude for their kindly and generous response.

I am sure that it is an encouragement to us all that the medical profession is so loyally supporting the Royal Medical Benevolent Fund and enabling the good work to be carried on at the present time, when the hardships of many are very great.—I am, etc.,

Royal Medical Benevolent Fund, 1, Balliol House, Manorfields, Putney, *London, S.W.15, Jan. 1.* THOS. BARLOW, President.

Tuberculosis and Shelters

SIR,—The issue of Circular 2231 of the Ministry of Health, which deals *inter alia* with the question of tuberculous persons frequenting shelters, compels me to return to some of the points raised in my letter published in your issue of November 2, 1940 (p. 608).

Naturally I welcome the fact that serious consideration is now being given to the danger to the general public. I regret, however, that in the accompanying letter from the Chief Medical Officer the danger to the patient appears to be considered chiefly from the angle of persuading him not to frequent public shelters and that the provision of satisfactory alternatives which will not be detrimental to his own or his family's health has received scant attention. To ask a tuberculous patient and family to use Anderson shelters is to court disaster only secondary in degree to the risk involved in the use of crowded public shelters. The conditions in an Anderson shelter, damp and badly ventilated, are conducive to cough, and the crowding of the family into such a confined space exposes susceptible persons to concentrated risk. Such a policy is directly contrary to all that the tuberculosis service has tried to achieve in recent years in the way of relative isolation of infectious cases, and I for one will take no part in it. It is unreasonable, on the other hand, even if an Anderson shelter were not harmful to the patient himself, to expect him or her to occupy it alone.

With regard to compulsory removal to hospital, I know that the London County Council is trying to increase its bed accommodation to meet the anticipated need, but at the present time it is often a matter of considerable difficulty to get hospital vacancies even for willing patients. Moreover, with the incessant propaganda about the supposedly deliberate bombing of hospitals and the undoubted fact that many of the hospitals are situated in vulnerable areas, it is becoming more difficult to persuade patients to enter hospitals at all willingly.

Tuberculous patients are human and are generally recognized to be more emotionally unstable than the average person. They want security as much as anyone else. The realist solution is to allocate or provide adequate relatively safe shelters for tuberculous patients which will be attractive enough to overcome the dislike of segregation. Otherwise there will be an increased tendency to the hiding of the disease, the conversion of the tuberculosis officer into a policeman, and the disappearance of patients from dispensary supervision.

In London, particularly in the City and surrounding boroughs, there is still a large number of relatively safe buildings not yet fully utilized where it would be possible to establish something in the nature of "night sanatoria," which would probably obviate the necessity for compulsory removal to hospital with its resultant congestion of beds and the confinement of ambulant patients for unlimited periods in wards which would become little more than prisons. The good will and co-operation of patients would be more easily secured if they felt that something was being done for them and the public would be more fully protected.—I am, etc.,

London, E.2, Dec. 30. C. K. CULLEN.

The Problem of the Shelters

SIR,—It appears that Mr. H. Mason (December 28, p. 917) does not realize that the two-stage or Haldane shelter, recommended by the A.R.P. Co-ordinating Committee, is not a "deep" shelter. As shown in the plans, it is a surface shelter, although it may be built below ground. Drainage should therefore present no difficulty. Mr. Mason may think that the adoption of this type of shelter would be disastrous; but it has been passed by the Ministry of Home Security as eligible for grant to local authorities. Also it is recommended by the Association of Architects, Surveyors, and Technical Assistants.

The shortage of labour and material mentioned by Mr. Mason provides a strong argument in favour of large communal shelters, since the larger the shelter the less is the material needed to provide a given standard of protection. A shelter in every home would provide many advantages: but the labour and material required to provide adequate protection would be prohibitive.—I am, etc.,

Jan. 2. J. R. MARRACK.

Convulsion Therapy in Out-patient Department

SIR,—Dr. E. Cunningham Dax's case (December 21, p. 878) against the treatment of out-patients by electrically induced convulsions is strongly supported by the following.

A spinster aged 46, described as a healthy person and as a popular and keen school-teacher before her present illness, became depressed after her mother's death in January, 1940. She lost weight, seemed apathetic, and reproached herself for imaginary neglectfulness and sins. When admitted to the Crichton Royal in May, 1940, she was agitated and sleepless. She constantly talked about her worthless and sinful life, blamed herself for her mother's death, and was sure that the police suspected and persecuted her. There were no physical findings except for a blood pressure of 166/90. Convulsion therapy seemed indicated because of the excellent results we had from it in similar cases of involutional melancholia. Between June 6 and 21 the patient received eight injections of triazol (azoman), six of which produced epileptic fits. The dose required for a complete reaction was 2 c.cm. of the 5% solution. There was some restlessness after the injections not followed by a fit; on three occasions the fit came on after a delay of some five to ten minutes. Nothing unusual was observed. After four fits the patient showed definite improvement; she seemed much more settled, conversed rationally, and was able to attend occupational therapy. Early in July she began to relapse. Delusions returned and were freely expressed; she made two suicidal attempts, and again became restless, although not to the extent she was on admission. The following four months brought no change. As the patient dreaded further injections, it was decided to apply electrically induced convulsions. Using the method and machine described by Fleming, Golla, and Walter (*Lancet*, 1939, **2**, 1353), she was treated with increasing doses on December 13, 16, and 18. Each day two attempts were made and none was followed by an immediate fit; but half an hour after the first treatment the patient, having meanwhile walked back to her wards, had a typical major fit while sitting at the fireside. Nothing happened after the two trials on December 16. On December 18 she had the maximum dose twice (duration 0.5 second, scale reading 100, resistance 550 and 450 ohms). A first fit occurred three hours and a second one approximately eighteen hours after the application of the electric current. On December 22 the blood pressure was 160/105.

This may be a unique observation; we have seen nothing similar among sixty patients treated by this method at the Crichton Royal up to the present. However, confusional states with or without aggressiveness and violence, exacerbations of depressive or manic episodes are not rare, and justify Dr. Dax's warning against the light-hearted application of the method. Much as I agree with this point of his letter, I cannot see why one should not make full use of the opportunity provided by convulsion therapy to teach students the differential diagnosis and treatment of the epileptic fit, so important in general practice.—I am, etc.,

Dumfries, Dec. 27. W. MAYER-GROSS.

Closed-plaster Treatment of Wounds

SIR,—The admirers of the genius of Prof. Rutherford Morison are indebted to Dr. Wm. McKenzie (December 28, p. 917) for his pertinacity in advocating the recognition of Morison's work. When home on leave during the last war I saw some of Morison's original bipp cases under treatment; these included patients with compound fractures who had lain out "in no-man's land" in Flanders from two to five days before treatment was initiated. The results of the treatment were remarkable; in fact they were startling. Morison claimed, and justly claimed, that he had discovered a new principle in surgery, where for the first time a septic wound could be successfully treated, sutured up without drainage, and remain undisturbed for several weeks. It is suggested that bipp only acts as a deodorant; such a statement is wholely incorrect. Morison claimed that the therapeutic effect of bipp was due to nitrous oxide liberated from the bismuth subnitrate, which acts upon the iodoform, thus liberating a constant flow of free iodine in the wound. And it was the constant action of this free iodine that had the beneficial effect.

That the bipp technique has not been more widely employed is entirely explained by the failure of those using it to carry out the technique correctly, as laid down by Morison. The surgeons who have not met with success were those who tried to improve on the procedure by washing out the wound with antiseptics of various kinds. Had these surgeons adhered to Morison's detailed technique of using a 1 in 20 solution of carbolic acid for the *outside* of the wound, and only allowing spirit. vini rect. *inside* the wound, how different would have been their results! To crab the method when the correct technique was not followed is so unfair; success can usually be assured if Morison's technique is followed without variation. The dispensing of the bipp is an important detail. The proper consistency of bipp is that it should be gritty when rubbed between finger and thumb. If too much paraffin is used the paste is too greasy; it will not adhere to a wound surface, so it cannot act; therefore bipp made up in a collapsible tube is useless. It should be stored in porcelain containers.

Morison always stressed the necessity for excising dead or damaged tissues as part of his technique, and that the bipp be rubbed into the tissues, any excess of the paste being removed before closure of the wound. All injured and treated limbs were fixed by firm bandages or by splints or by plaster-of-Paris. After my return home from the last war in 1919 I carried out Morison's technique in my emergency operations associated with sepsis at the Royal Victoria Infirmary, Newcastle-upon-Tyne, particularly in cases of appendix abscesses. During the operation the cut abdominal wall muscles were mopped with methylated spirit and scrubbed with bipp before the abscess was opened into, with wonderful results. After practising this method for six months I reverted to the old method in these cases. Two weeks later the sisters of my male and female wards jointly asked if I would resume the bipp treatment, for two reasons: (1) the less work entailed for dressings, which was once every two to three days in the bipp case compared with once every four to six hours in a non-bipped case; and (2) the lessened cost of dressings in the bipp cases. Further, every compound fracture since the same date has been treated by the bipp technique and the wound closed without drainage: in no single case have I had cause to regret the absence of a drain.

Prof. Morison discovered and practised a new principle in surgery, which included excising the damaged or dead tissue, closure of the wound without drainage, fixation of the damaged part, together with the application of an antiseptic paste from which comes a continual beneficent emanation of free iodine. I consider he was a pioneer in all these points and should not be deprived of the full credit for them.—I am, etc.,

Newcastle-upon-Tyne, Jan. 2. R. J. WILLAN.

SIR,—The application of the term "closed-plaster treatment" to the method associated with the name of Winnett Orr is unfortunate, as emphasizing, at the expense of fundamental principles, one detail of technique, and that a not universally satisfactory one. The undoubted success of the method depends on the application of these surgical principles: (1) excision of the wound in suitable cases, with removal of foreign bodies; (2) the establishment of free drainage, the wound being left widely open; (3) the avoidance of unsuitable antiseptics; (4) immobilization; and (5) avoidance of frequent dressings. The importance of immobilization can scarcely be over-estimated, but plaster is not always a wise method of fixation, especially if the circulation is in doubt. If a plaster is used it should not necessarily be of the closed type, notably if excision has been imperfect or skeletal traction has been applied.

The object of this letter is not to decry the use of plasters in general or of closed plasters in particular—far from it—but to condemn the implication in the term "closed-plaster treat-

ment" as applied to the present-day treatment of wounds. Unfortunately it has been observed that closed plasters are sometimes being used without thought of surgical principles.—I am, etc.,

Dec. 28, 1940 H. JACKSON BURROWS.

Hospital Infection of War Wounds

SIR,—I have read with particular interest Prof. A. A. Miles and his colleagues' interim report on hospital infection of war wounds (December 21 (p. 855) and 28, 1940 (p. 895)) and your leading article on the subject (p. 908). The open ward, housing a number of patients, favours cross-infection. This fact is well known to those in charge of fever hospitals. It has been found that the relapses of scarlet fever cases during the third to the sixth week are mainly due to a reinfection with a different serological type haemolytic streptococcus. These relapses can be prevented by an "aseptic" technique of nursing and the precaution of treating the patient in the cell of a chamber-ward. This type of ward is probably the ward of the future for both fever and surgical cases. The time has come when we should radically alter our conception of the design of hospital wards. The lesson which we are now re-learning should not be again lost when we start rebuilding our hospitals.—I am, etc.,

G. E. DONOVAN.
Gorseinon, Swansea, Dec. 30. Medical Officer of Health.

Sulphonamides in Treatment of Bacillary Dysentery

SIR,—Dr. J. Drummond's letter (September 14, p. 367) reminds me of a case I saw in July last which may be worth mentioning. The patient was an American negro in the City Hospital, Welfare Island, New York City, and when I saw him he had been there about ten weeks, I believe. He had dysentery with only about four or five motions a day, all containing blood and mucus, which no form of treatment did the slightest good to; *B. flexner* had been cultured from the stool. The most alarming feature, however, was a swinging temperature rising to 102° F. or 103° F. every day. He had had serum, salines, kaolin, intestinal "antiseptics," and many other forms of treatment. The doctor in charge of him, Dr. Greisman (I believe at the suggestion of the house-physician), decided that there could be no harm in trying sulphapyridine, and the patient was given 3 grammes a day. From the next day the temperature never rose again, and the dysentery stopped abruptly. The man was quite well a couple of weeks later, but I do not know the subsequent history.

I may mention that I have not been able to duplicate this happy result in this country. In fact, cases of bacillary dysentery to which I have given sulphapyridine and sulphanilamide have shown no improvement at all.—I am, etc.,

S. BETTENCOURT-GOMES.
Demerara, British Guiana, Nov. 23, 1940.

A Sound Wartime Dietary

SIR,—As the most wholesome, *complete* diet, known to have bred a race strong in brawn and brain, there is everything good to be said for the Scottish ploughman's "filling" fare of oatmeal made into porridge, brose, or bannock, broths in quantity containing any and every root and green vegetable, and potatoes cooked in several simple ways, commonly stoved with fat and onions, these washed down with a flagon of milk: a diet costing him exactly nothing in cash! On occasion he was known to allow himself the luxury of a red herring. On this diet Robert Burns, that prince among poets, was nurtured, and subsisted all his days.—I am, etc.,

Bournemouth, Jan. 1. S. WATSON SMITH.

Oranges and Tomatoes for Infants

SIR,—The present shortage of oranges creates a problem in infant nutrition. May I suggest that you make known through the Press, etc., how important it is that what oranges are available should, if possible, be reserved for babies.

The use of tomato juice as an alternative is not sufficiently known to mothers, although supplies of this, even in tinned form, are, I believe, limited; but the knowledge of this fact and the restricted use by the general public of oranges may save a number of wartime babies from nutritional deficiency diseases.—I am, etc.,

Reading, Dec. 27. W. IVOR BAIN.

The Shock of the Ambulance Journey

SIR,—Mr. D. G. Duff (November 9, p. 647) writes to say: "I am not certain that, even at this stage of the war, it is fully realized how shock-producing an ambulance journey may be." This fact was well recognized in the war of 1914–18, and has been ever since a part of the R.A.M.C. training. In the *Journal of the Royal Army Medical Corps* of last September I stated in this connexion: "All transport must be as smooth as possible. Smooth running can be helped by reducing the pressure of tyres over bumpy roads. The speed of the ambulance should vary according to the surface; bends and corners should be approached at a speed that will not cause swaying of the vehicle. Loading and unloading must be carried out as gently as possible, and the patient must never be submitted to sudden jars."

I have quoted this because from Mr. Duff's statement it is obvious that the present organization for distributing medical knowledge to all practitioners is not sufficient. No doctor takes all the medical journals, and in consequence a number of doctors never have the opportunity of getting to know about some new and important medical knowledge for a long while after it has become the common property of a few. In the meantime their patients fail to benefit from this new knowledge as quickly as they have a right to expect. This brings up the point that complete co-operation for the common good among the medical profession is not catered for at present. This could be altered if a committee was appointed to sift all new medical knowledge, and their findings be published in all medical journals.

At the moment, would it not be advisable to publish in all the journals an authoritative statement on the treatment of war casualties as it affects all doctors, and not from any one specialist's point of view? This should also include exactly what to teach as first aid, as it appears that in this connexion "a little learning is a dangerous thing."—I am, etc.,

R. R. G. ATKINS,
Dec. 3. Colonel, R.A.M.C.

The Methods of Statistics

SIR,—In times of national stress it is sometimes suggested that the medical profession ought to play a larger part in dealing with the nation's problems. It is easy to understand anyone taking this view, but less easy to see the part that individual members of the profession might be expected to play. It can hardly be doubted that a satisfactory solution of many of the nation's problems necessitates a great amount of preliminary research over wide fields, both medical and economic, and it is to be expected that in the post-war years the need for research will be greatly increased. In his fairly recent *Philosophy* Prof. H. Levy stresses the need for widespread research, and specifies a number of "social variables" requiring investigation in the interests of mankind.

Possibly the best contribution medical practitioners could make towards the solution of national problems would be to convince themselves of the urgent need for research, and to use their special opportunities to rouse the interest of others with a view to getting this carried out. Unfortunately statistical investigations often fail to interest those who have no knowledge of the method of statistics. A knowledge of these methods, on the other hand, often creates an interest in research. At present there is evidence of a desire on the part of the lay public to know something of the methods of statistics. At Glasgow a course of twelve lectures on the subject is open to the public, and no doubt similar courses for the public are being given elsewhere. In the medical profession, apart from those engaged in public health or in research, it can hardly be said as yet that a knowledge of these methods is widespread.

It is possible that the time will come when medical students will be required to have some knowledge of them as part of their educational equipment. A preliminary course of

instruction, given in association with the lectures in biology, would have some value in developing the critical faculties of the student. There are, perhaps, few of the later subjects in the medical curriculum which could not be revitalized to some extent and pruned of some unnecessary dogmatism by frequent reference to some of the concepts of statistical theory. It would be an advantage for the student to be introduced to the subject at a time when he has not yet begun to forget his mathematics. Once he has realized that he is acquiring an instrument that may be of service to him throughout his career, he may feel the urge to follow up the subject in the interesting and hitherto fruitful field of statistical mathematics. Here he may find beneficial mental discipline and, perhaps, aesthetic satisfactions. Others would at least learn enough perhaps to appreciate the advantages of taking a special course later. Even if the student should never have occasion to carry out a single statistical investigation of his own, his instruction in the methods will have been justified if he has been enabled thereby to take an interest in the researches of others, medical or otherwise, and to appreciate the implications of their results.—I am, etc.,

Paisley, Dec. 28. A. GARDNER.

Local Injections in Muscular Rheumatism

SIR,—I was very much interested in an article by Mr. Martin Button on local injection as a means of rapid restoration of function in muscular rheumatism (August 10, p. 183). For the last three months I have also treated by this method about twenty cases of lumbago, one case of sciatica, two cases of supraorbital neuralgia, and one case of severe muscular spasm of the flexor sublimis digitorum, with excellent and, as Mr. Button rightly says, surprisingly quick results. Instead, however, of using large quantities of novutox, as Mr. Button does, I have been able to get very good results by small injections of the oily preparation of Allen and Hanbury known as proctocaine. Of this I have never used more than 1½ c.cm., while in most cases I have used much less, the largest quantity being required in cases of lumbago.

In selecting the sites for injections in lumbago I have found Mr. Button's method the best. I generally ask patients as to the one position which brings on maximum pain on movement, and then mark out points of maximum tenderness on deep pressure (there are generally more than one); exact location of these is of great importance in getting the best results. Having obtained these, and with careful skin sterilization, I inject about 5 to 6 minims into the muscle substance with a needle, going at least half an inch deep vertically. At each of these tender points the process is repeated. Then the injected parts are well massaged and a collodion or benzoin dressing put on. The patient is then asked to get up and told to assume the position which gave him acute pain before the injection. His relief and surprise are extreme when he finds the pain almost gone. He is then made to do an exercise which in India is known as "oothbess," which is to sit on one's haunches and get up, doing that several times. Patients who come to the out-patient department walking with the greatest difficulty on sticks, doubled up with pain, have left walking straight without support after the injection. Of all the cases of lumbago on which I have tried this treatment I have not yet had a single failure. The injection itself is not at all painful, as Mr. Button finds with nuvotox, and that, I believe, is owing to the absence of adrenaline in proctocaine.

The two cases of supraorbital neuralgia were very bad cases. In one a young Mohammedan lad of 20 said: "For the last fifteen days I have night and day a pain in the right side above the eye, and about midnight I get it so intense that I am like a madman, waking up the whole house, allowing nobody to sleep." He was locally treated with heat diathermy, etc., but with no benefit, and analgesics and sedatives had no beneficial effects. After making sure that no frontal sinus or antrum infection was responsible for the pain, I injected only about 2 minims of the proctocaine solution as deep as I could go under the skin, obliquely with the needle pointing upwards and outwards just a little above the supraorbital notch. The part was then massaged. The next day he came quite relieved of his pain, having slept the first night peacefully. There was some swelling in the region of the injection and a slight puffiness of the upper lid; these all disappeared in two days, and he has not so far (after two months) had a relapse. Another case was of a similar nature and got immediate relief, but a month later there was a slight relapse, which, however, was controlled by soda salicylates in large doses.

The sciatica case, as Mr. Button terms it "pseudo-sciatica," was of two months' duration, and one injection of 1 c.cm. sufficed to relieve the pain. I have not yet tried so far the remedy in stiff neck cases nor in deltoid rheumatism, and was much interested in Mr. Button's experience of such cases.—I am, etc.,

Bombay, Nov. 11. N. H. VAKEEL.

"Egyptian Tummy"

SIR,—Dr. H. M. Stanley Turner (December 14, p. 850) rightly states that I ascribe this ailment to meteorological causes—that is, to a low relative humidity and active chilling of the body surface (December 7, p. 806). A similar ailment in Northern Egypt, he states, is due to a mild bacillary dysentery—usually the Flexner γ bacillus. I cannot state whether this bacillus was or was not present in any of my cases in Upper Egypt, as no bacteriological examination was ever made of the stools, as I always found that the treatment I have indicated cured and prevented these ailments in a short time provided that steps were taken to prevent the action of the climatic conditions to which I have drawn attention.

I will illustrate this by a case at Assuan of this ailment, treated at first by a colleague. The patient was a lady travelling with a friend, who acted as nurse. After some days' illness I was asked by them to come to see her; meeting my colleague, I informed him of this request. He said, "Do so by all means; it won't make any difference, as she will die in the night"; and the next day a consultant physician resident in Assuan told me he had taken a very serious view also of the case. I found the patient weak and in distress from very frequent stools, with mucus and blood. To my amazement she was lying in a thin nightdress, perspiring, on the bed; the cold north wind, entering by a window, passed across her body and out by an open south window. A warm Turkish towel was ordered to be fixed round the abdomen, and treatment and diet as suggested in my previous letter were instituted. She recovered completely, and I dined with her and her friend some eight to ten days later.

I still maintain the climate is the determining cause of the illness and its course.—I am, etc.,

Dec. 24. LEIGH CANNEY.

SIR,—From severe personal experience of "gippy tummy" in the early days of my service in Egypt I found that the condition arose as a result of nocturnal abdominal chill. In the Nile Valley and adjoining desert there are very great daily variations of temperature up to as much as 60° between the maximum and minimum in twenty-four hours.

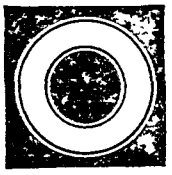
After experimenting I found that the condition did not occur if I wore a cholera belt from sundown right through the night, and once I had made this discovery my troubles were over. I also persuaded a number of other sufferers to do the same, and I never found it necessary to order special diets, to give medicines, or to recommend removal from the climate of Egypt or the Sudan. The cholera belt can be improvised out of towelling, a scarf, or any other material that can be wound round the abdomen, and nothing else is needed to prevent this tiresome, "colicky," urgent intestinal upset. Natives often use their turbans to protect the abdomen at night.—I am, etc.,

Dec. 31. V. S. HODSON.

Euthanasia

SIR,—I do not suppose you would wish for much discussion of this problem at the present time. I feel, however, that the collective wisdom of experienced family doctors has never been sought. They alone have the practical and expert knowledge. I believe the majority of them would see little need for legalization, and could find many convincing arguments against it.

hormone therapy in BURNS & SCALDS



". . . During the past five years 76 burns and 322 scalds have been treated by one unit in the Royal Hospital for Sick Children." *(By various methods).* "The average age of the patients was 2½ years . . .

". . . The results during the past year have completely justified the use of a side ward solely for the treatment of burns and scalds.

"Desoxycorticosterone acetate* has proved very valuable in the treatment of toxæmia, and I advocate its use in all cases which develop this complication of burns."

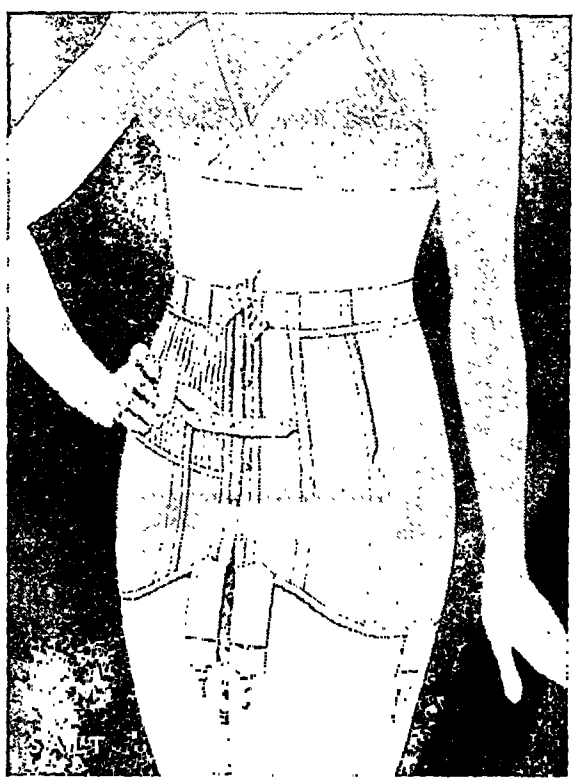
SURGICAL SERVICE
SALTAIR



Support for Nephroptosis

IS COMBINED WITH THE STYLE THE PATIENT PREFERS

in

SALT'S PATENT KIDNEY CORSET

The great majority of medical men are by now well aware that Salt's patent Kidney Belt has come to be accepted as the standard appliance for use in cases of mobile kidney. But many patients prefer corsets to belts, and it is for them that Salt's patent Kidney Corset is made as an alternative. Only in the matter of style does it differ from the Kidney Belt—in all other respects appertaining to supporting and corrective properties it is identical with the Belt. Symptoms due to dragging on the renal ligaments are obviated; the danger of hydronephrosis, produced by kinking of the ureter, is considerably diminished. Salt's Corset & Belt Book gives fuller details. May we send you a copy of this well-known publication?—free and post free, of course.

SALT & SON LTD BIRMINGHAM 2.

An inevitably fatal result can perhaps be diagnosed with reasonable certainty. Pain cannot be assessed by the doctor, but it can be relieved. Misery and the desire to be put out of it have little relation to actual pain; they are not constant from day to day, and are expressed many times without real inward conviction; they may be dispelled by a happy chat about old times. An invalid, like a child, may have the whole mental outlook influenced by those around. Discomfort, almost unbearable, is relieved by improved nursing. Mental distress may be a reflection from or on those who are in charge.

Pain in malignant disease may be severe, but in many cases this is not for very long periods; the case may drift on to a stage when there is much less pain but there is a desire for morphine. If the patient knows that reasonable dosage will be forthcoming at the right time, but understands the wisdom of spacing it out, there will not be so much evidence of apparent pain. It is true that this may leave a poor hopeless specimen being doctored and nursed, but both these professions gain something by rising to the occasion. They need not try to prolong a life that is coming to a natural end. If voluntary euthanasia were made legal, there is another side to the picture. A doctor dealing with an urgent, hopeless case might have less freedom with regard to dosage if some judicial authority were in the background, jealous of prerogative. The family doctor could recount some strange social complications—for example, in relation to re-marriage—and there may be legal responsibilities about the date of decease. Social and important economic problems are capable of being solved legally, but they might lead to social and mental ruin of someone left behind, who, with altruistic motives at the time, had acted on narrow, limited medical advice.

With regard to hospital cases the question of publicity and reputation is all-important. It is possible that one group of hospitals would decline to undertake the responsibility, and another group, who felt they were doing the right thing in giving the facility for euthanasia, might be placed in a difficult position in the matter of their good name for sympathetic nursing and their prestige. If practically all hospitals and most of the profession become more closely associated with the State, it might be unwise to bring forward legislation for a contingency which arises rarely and does not depend entirely on the natural history of the disease in question.

I am so convinced that the majority of good general practitioners would not countenance voluntary euthanasia that I believe many of them would feel compelled to set up some organization which bound them not to be associated with it, so that they would be protected from the many difficulties which they and their patients might otherwise fall in with if euthanasia were legalized. I believe that a wise patient who really understood would not subject his relatives or medical advisers to making a decision the responsibilities of which would live when he had passed away.—I am, etc.,

Derby, Dec. 27. HUGH BARBER.

SIR,—Dr. D. Kelleher (December 21, p. 880) suggests that the problem of the "incurable person in pain can be very simply overcome by the giving of morphine," and he goes on to argue from this that euthanasia is wrong. Surely this is not quite the way to look at it. The giving of ever-increasing doses of morphine becomes anything but simple, and the state of the morphine-poisoned patient is very pitiable. In the end the patient dies of morphine poisoning—a very barbarous form of euthanasia.

This matter is one of very great importance, not only for the patient with incurable painful disease but still more so in the case of idiot children. I feel, when I visit one of the homes where these little sufferers are boarded out, that their continued existence cries for action. I think there are very few people who would wish to prolong these lives if they could but see some of the cases.

It is because human life is so sacred that some people feel that no travesty of it should be allowed to continue. It is, admittedly, a very large and difficult question, but it is not too soon for the gravest thoughts and consideration to be given to it.—I am, etc.,

Hendon, N.W.4, Jan. 1. R. W. COCKSHUT

[*** This correspondence is now closed.—ED., *B.M.J.*]

Adrenaline in Asthma

SIR,—I have read with interest Dr. George Krasner's letter (November 16, p. 684) on the treatment of adrenaline-resistant cases of status asthmaticus, and I note that a correspondent confirms that such cases occur. I have had such a case, which did not improve in the slightest under the method suggested by Sir Arthur Hurst, and in which, after warning the relatives of the dangers of morphine, the latter was used, and for a time the patient—apart from the asthma—was gravely ill as a result. Sir Arthur does not mention any failures with his regime, and one would be interested to hear whether he has anything to suggest, if he has had any.

Finally, Dr. Krasner mentions more than one method of treatment, so presumably, as is to be expected when asthma has different causes, none of these is infallible in any one case. It would be of general interest, no doubt, if Dr. Krasner could be invited to explain the following points: (1) Can the pathological conditions which cause the different types of status asthmaticus be diagnosed clinically from the history or examination? (2) If so, are any of the different methods of treatment applicable particularly to a particular pathological state? (3) Are there any other indications for the selection of the method of treatment, any contraindications, or anything noteworthy in the method of administration?—I am, etc.,

Edinburgh, Dec. 17. M. PARK.

Medical Examination of the Home Guard

SIR,—I have been surprised that there has been no medical examination of recruits for the Home Guard. We are told that the Home Guard is the second line of defence in the event of invasion, and, if so, it is reasonable to expect that our defenders shall be sufficiently fit physically and mentally to carry out their duties. At present, from my own experience in a country district, anyone volunteering for the Home Guard is accepted.—I am, etc.,

Llanfyllin, Dec. 18. L. J. FORMAN BELL.

Pathogenesis of Non-pulmonary Tuberculosis

SIR,—May I correct an error which inadvertently crept into my article on the "Pathogenesis of Non-pulmonary Tuberculosis" (November 16, p. 660), and refer also to two matters discussed by correspondents?

A follow-up report was obtained concerning eighty-one of 110 patients suffering from tuberculous cervical adenitis and twenty of forty patients suffering from tuberculous abdominal glands, a total of 101 follow-up reports, not eighty-one as stated. These follow-up reports were completed towards the end of 1938, and although they referred to patients discharged from several months to seven years before that date, no further development of disease in these patients has come to my notice during the ensuing two yeras.

Drs. F. A. H. Simmonds and Brian C. Thompson (November 30, p. 766) refer to Dr. Thompson's exhaustive and accurate study of 324 patients suffering from tuberculous adenitis, and quote it to refute my suggestion that "patients suffering from gross tuberculous adenitis do not under favourable conditions develop tuberculosis in other parts of the body." In his article, however, Dr. Thompson emphasizes the very unfavourable economic conditions prevailing in the area from which his cases were drawn. He adds that only 109 of his 324 patients were admitted to hospital or sanatorium for observation or treatment. The conditions, therefore, were very unfavourable. The distinction I wished to draw is easily demonstrable in a sanatorium in which both pulmonary and non-pulmonary tuberculosis are treated. Many children have been treated here for tuberculous adenitis during the past ten years; many young adults unfortunately are still being admitted suffering from phthisis, but none of these are the children whom we treated for tuberculous adenitis.

Dr. A. G. Auld's experience (December 7, p. 808) of a patient whose pulmonary tuberculosis abated after the incursion of the complication of tuberculous lymphadenitis is interesting. I have looked through the register of more than 4,000 patients who have been admitted to this sanatorium during the past ten years, and found record of only one patient classed as

"T.B. + 11," who had a tuberculous cervical gland. I venture the opinion that Dr. Auld was right when he attributed significance to his case.—I am, etc.,

M. C. WILKINSON,
Medical Superintendent.

The Sanatorium, Black Notley, Braintree; Dec. 18.

Rationalization of the British Drug Industry

SIR,—Much can be said about the annotation entitled "Rationalization of the British Drug Industry" which appeared in your issue of December 21 (p. 875), and I would like to draw your attention to the following points.

Whatever may be said about the names adopted in the Addendum to the *B.P.*, they must be admitted as being reasonably terse and sufficiently indicative of the products to render them really useful, but if the medical profession has a preference for the original German titles we might well ask why they have not adopted them, as was the case with aspirin during the last war. Really the medical profession has not shown very much interest in the niceties of pharmaceutical nomenclature. For instance, those acquainted with hospital practice will know that some eight years of official recognition of posterior pituitary extract and neoarsphenamine has made no difference to the names used in the wards, or, for that matter, those taught in some medical schools.

One admits, of course, that there is a valid argument against the use of a proprietary title for an official drug, or even for any new substance discovered by research workers in a hospital or a university laboratory, and the only remedy would appear to be for such institutions to patent the results of their researches and control any commercialization that may follow, as has been done with insulin. But one need only to cite the instances of halibut-liver oil and the new remedy for epilepsy to show that our commercial laboratories are just as likely to be affected in this way as those institutions we have mentioned. The problem of chemotherapeutic research is not going to be solved by the efforts of the Medical Research Council alone without taking into consideration the activities of the commercial laboratories in this country, some of which have the advantage of being able to call upon the medical knowledge and research available in American scientific institutions.

Another reference in the annotation which should be commented upon is that which points out that "soon after the outbreak of war the Board of Trade decreed that every industry must organize itself for export trade. Despite all this, the British drug trade remains a complex of belligerent minor States." It concludes by saying that "some order of rationalization must be carried out. . . . People who do not make order by their own efforts may have a new order forced upon them." The industry is taking every possible advantage of the present circumstances in its organization for the export trade, but it should be borne in mind that it takes more than a year to counteract all the effects of unrestricted foreign competition. The economies of the Nazi export trade are well known, and it is hardly likely that such a regime would be tolerated in this country.

Much more could be said, but it seems to us that many of the points raised are governed by higher politics and are outside the range of discussion.—I am, etc.,

P. ROCHE,
Editor, *Retail Chemist.*

Dec. 31.

Lymphatic Circulation in Septic Inflammation

SIR,—Since Trueta and Barnes (July 13, 1940, p. 46) propounded the theory that the principal advantage of the closed-plaster method lay in the production of lymph stasis, it has been evident that this unusual evaluation of the lymph flow in septic infection could hardly go unchallenged. The letter from Mr. A. C. F. Halford (December 28, 1940, p. 918), together with your illuminating leader on the subject (December 7, 1940, p. 788), embolden me to suggest that the effect of the closed-plaster method on the lymphatic circulation must be totally different from that envisaged by Trueta and Barnes. In attempting to explain the result of hypertonic sodium sulphate applied to a wound (*Lancet*, 1940, **1**, 216) I suggested indeed exactly the opposite—namely, that one of the chief virtues of this treatment lay in the reduction of oedema and improved lymphatic circulation by the clearing of the lymph spaces and capillaries, resulting from the osmotic shrinkage of the endothelial cells. Now, no one who has heard Trueta lecture and seen the results of the closed-plaster method can fail to be impressed with the success of this treatment. How, then, can these opposing theories be reconciled?

The normal lymph flow along the lymphatics depends upon two factors: (*a*) *vis a tergo*, in the shape of pressure of lymph in the intercellular spaces; (*b*) alternate squeezing and expansion of the lymphatic vessels. The latter depends upon two forces: (1) movements of neighbouring muscles; (2) pulsation of neighbouring arteries. In plaster fixation, with a limb wholly or partly enclosed in a rigid case, I suggest that the effect upon these factors will be as follows: (*a*) the *vis a tergo* is assisted, whatever the force with which the lymph is exuded from the blood capillaries; this force will be more directly conveyed to the lymphatic vessels in a closed space. (*b*) Although muscular movement is largely excluded the pulsation of the arteries will be communicated with special force to the lymphatics inside the plaster case.

Further, little attention seems to have been paid to the osmotic conditions obtaining inside a plaster case. Actually, we have a state of affairs in which any liquid exuded near the plaster is exposed to partial evaporation. The liquids to consider are lymph (or pus) and sweat (when uninjured skin is covered). Both these, when exposed to evaporation, must become of a much higher osmotic value than the cytoplasm of adjacent cells, so I further suggest that we have here a mild hypertonic type of treatment, with a consequent shrinkage of cells swollen by the action of bacterial toxins, and the clearing of the lymph channels previously described in connexion with hypertonic sodium sulphate. I therefore suggest that, far from causing stasis of the lymph, the closed-plaster method must have the opposite effect and promote a steady flow of lymph from the tissues similar to that promoted by the use of hypertonic sodium sulphate.

Wherein, then, lies the virtue of immobilization of an injured part, whether by plaster or otherwise? Here I suggest that we have tended to confuse flow of lymph with spread of live bacteria, and to regard the two as necessarily concomitant. As you justly point out in your leader, muscular movement and manipulation tend to damage already weakened lymphatic capillaries, and so spread infection. But in the absence of such movement the bacteria probably remain caught up locally in and among the tissue cells, and the steady flow of lymph into and out of the tissues is wholly beneficial. Hence any line of treatment which promotes the latter without causing the former is all to the good; and the advantages of the closed-plaster treatment of a whole limb, and of hypertonic sodium sulphate treatment directed to a wound, are explained.—I am, etc.,

J. C. LYTH.

York, Jan 2.

Human Fertility

SIR,—Dr. John Pryde's contribution to the study of human fertility (January 4, p. 12) is of such general interest and importance that it must produce controversy, in spite of his wishes. Two practical points are concerned. First, if pregnancy is desired coitus should occur during the fertile period—namely, between the tenth and fifteenth days of the menstrual cycle. Secondly, if pregnancy is not desired can we with any degree of certainty advise our patients that it will not take place so long as they abstain from intercourse during this portion of the menstrual cycle—in other words, is abstinence during this time a certain contraceptive? Dr. Pryde's cases support his idea, but the following, the authenticity of which I can guarantee, do not.

Case 1.—Cycle regular 5/28; husband away for three months, returning on the twenty-sixth day of the cycle. Coitus took place that night; no period occurred two days later and pregnancy resulted. Friedman test positive three weeks later. In this case both parties were doctors and realized the importance of the information given.

Case 2.—Cycle 3-4/28-30. Married on sixth day of cycle, following a normal period. No coitus before marriage, husband called up to join the Army two days later. Pregnancy resulted.

These cases are not quoted to belittle Dr Pryde's excellent article in any way, but further to stimulate investigation on this important problem in the manner suggested by him. As a result of such an investigation, carried out on a large number of cases, much valuable information may be obtained, among which may be found that many women from the ovulation point of view, behave like rabbits.—I am, etc.,

Oxford, Jan. 6. J. D. FLEW

Talipes Cavus

SIR,—Mr. W. Kent Hughes's article on talipes cavus (December 28, p. 902) was very interesting. I spent some time trying to understand his explanation of the clawing of toes in acquired pes cavus, but failed. He states that "clawing of the toes is attributed by some authors to paralysis of the interossei," and gives numerous points against this theory. Most authorities that I have heard on the subject believe that pes cavus may be due to paralysis or paresis of the lumbricales (not interossei). This explanation appeals to me as reasonable for two main reasons.

First, the deformity of the hand following an ulnar palsy is typical—the ring and little fingers are clawed whereas the index and middle fingers are not. Since the ulnar nerve supplies all the interossei, if Mr. Hughes's views were correct one would expect clawing of all the fingers. The lumbricales to the ring and little fingers are paralysed in an ulnar palsy and the corresponding fingers are clawed. *I think the condition in the foot is analogous.* Secondly, the operative procedure based upon the theory that clawing of the toes is due to paresis of the lumbricales has been used successfully on many cases at the Wingfield Hospital, Oxford. The operative *procedure is essentially a reconstruction* of the lumbricales by suturing the long flexor to the long extensor of the toes. The flexor is usually brought up along the medial side of the proximal phalanx and sutured to the extensor expansion over the distal end of the proximal phalanx. As soon as the suturing is finished the clawed toe should be perfectly straight.—I am, etc.,

Luton, Dec. 30. L. W. PLEWES.

Indian Medical Department

SIR,—With reference to the correspondence on the above subject may I exercise the privilege of disagreeing with a portion of the editorial note (December 14, p. 850). Your closing sentence is misleading. An Indian military hospital is for Indian troops, while a British military hospital is for British troops. Both, of course, are Indian in the sense that they are for use in India or elsewhere under the C.-in-C., India. The personnel of both or either may be British or Indian (vide the case of the Bengalee in the R.A.M.C. and of the Europeans in the I.M.S.). The test of the correct designation of the military hospitals in India would be to address a letter to the "Indian Military Hospital" in Barrackpore, for instance, and it would *not* be delivered at the British Military Hospital.

The matter of the qualifications of the military assistant surgeon class in the I.M.D. and their registration on the British *Register* is one that calls for some "searching of the heart" on the part of the General Medical Council. All these medical gentlemen undergo a full curriculum in recognized Indian universities but are debarred from British registration. Last week it was announced that the Government were giving sympathetic consideration to the registration of ex-enemy aliens, while other aliens were already admissible to the *Register*. What about these British practitioners in the I.M.D.? While not wishing to name any prominent medical men now in Britain, I would state that there are quite a number who have "pitched their tents" in the British Isles, and on the strength of their studies in India have obtained degrees and diplomas ranging from Oxford to any one of the corporations one cares to name. Might I ask that retired officers of the I.M.D. be allowed registration (for the duration), so that their wide experience in medicine and army administration may be used at the present time. Some of them could usefully do A.R.P. or locumtenent work for men on Service, and at the conclusion of hostilities they would not remain in competition with the returned Service officers, especially as they already enjoy Army pensions. A gesture of this nature calls for moral courage, and I do not think the Briton of 1940 lacks this prerequisite.—I am, etc.,

St. Helens, Dec. 16. DONALD CAMPBELL.

SIR,—*With reference to Sir Henry Gidney's letter about the* Indian Medical Department and your comments on the phrase "Indian Military Hospitals" (December 14, p. 850), I feel that this phrase is apt to be very misleading, as it has apparently been so with you. I shall be glad if you will allow me to clear up this definition in your columns.

The military hospitals in India are divided into two separate groups. One deals with British troops only, and the hospitals are termed the "British Military Hospitals," to which the Assistant Surgeon Branch of the I.M.D. is attached for duty. The other group deals with Indian troops only, and *the hospitals are termed the "Indian Military Hospitals,"* to which the Sub-Assistant-Surgeon Branch of the I.M.D. is attached. This branch is recruited from Indians only, who are given a medical school training only, whereas the Assistant Surgeon Branch is recruited from Europeans and Anglo-*Indians who have a university training.*—*I am, etc.,*

Maltby, Dec. 19. A. H. BARTLEY.

Universities and Colleges

UNIVERSITY OF OXFORD

B.M. and B.Ch. Examinations, 1941

The first examination for the degrees of B.M. and B.Ch. will be held on March 17, 19, 20, 21, 22, 24, and 25, and the second examination on March 31 and April 2, 3, and 4. Entries should reach the University Registry by 3 p.m. on February 22.

ROYAL COLLEGE OF SURGEONS OF ENGLAND

Lectures

The course of Hunterian Lectures for 1941 is arranged as follows: January 13, Prof. H. A. Harris, Growth in general; January 14, Prof. Harris, The anatomy and physiology of locomotion and posture; January 15, Prof. Harris, The inherent weakness of the human body with reference to orthopaedic practice; January 20, Mr. L. E. C. Norbury, Carcinoma of the rectum, with special reference to its pathology and treatment, based on a survey of cases at St. Mark's Hospital during the past ten years; January 22, Mr. Norman Capener, The lumbo-sacral joint: a discussion upon spondylolisthesis, scoliosis, and sciatica; January 24, Mr. R. E. Smith, The undescended testicle; January 27, Mr. H. A. Brittain, The principles of arthrodesis; January 29, Mr. J. M. Yoffey, The flow of lymph from the nasopharynx and the absorption of dyes, proteins, viruses, and bacteria after nasal instillation; January 31, Mr. W. H. Graham Jessop, The surgery of the great omentum; February 3, Mr. F. Ronald Edwards, Dried plasma: its preparation and administration for the syndrome of shock; February 10, Mr. F. F. Rundle, A study of the pathogenesis of thyrotoxicosis. On February 17 Dr. A. J. E. Cave will give the Arris and Gale Lectures on the comparative anatomy and evolution of the paranasal sinuses. All the above lectures begin at 3 p.m.

Prof. A. H. Burgess will deliver the Hunterian Oration on Thursday, February 13, at 2.30 p.m.

St. Thomas's Hospital Gazette has recently celebrated its Jubilee with the special issue for December, 1940. In spite of the war it still maintains the high standard of medical journalism it has always set before it, and the Jubilee number reproduces two photographs of the King and the Queen inspecting damage done to St. Thomas's Hospital during air raids on London.

Obituary

F. G. PROUDFOOT, M.D.

Consulting Obstetric Physician, Radcliffe Infirmary, Oxford

Dr. Frank Grégoire Proudfoot, who died on December 19, 1940, was born at St. Andrews on May 7, 1869, and was educated at Dumfries Academy and Madras College, St. Andrews, and at Edinburgh. He took his degree in Arts at St. Andrews in 1890 and graduated M.B., C.M. at Edinburgh in 1894, taking his M.D. of the latter university in 1910. After qualifying he was house-surgeon at the Royal Infirmary, Edinburgh, and later house-surgeon and house-physician at the Radcliffe Infirmary, Oxford, where he settled in private practice. Dr. Proudfoot was fortunate in his choice of Oxford at that particular period. The modern medical school was just beginning to make headway, having been stirred by the activity of Sir Henry Acland, and among Dr. Proudfoot's colleagues were Arthur Thomson and James Ritchie, both graduates of Edinburgh University. Dr. Proudfoot quickly established an extensive practice, and in due course became one of the best-known practitioners in Oxford and district. He early specialized in midwifery, and in 1920 had the satisfaction of witnessing the foundation of the Maternity Department of the Radcliffe Infirmary as a special unit. It is said that he paid the salary of the early house-physicians out of his own pocket. For many years he acted as honorary physician to the Maternity Department, and on his retirement was elected consulting physician there. Besides being consulting obstetrician to various local authorities, he was also examiner to the Central Midwives Board and to St. Andrews University in materia medica. In 1920 Dr. Proudfoot received the degree of M.A. (Oxon.), being the last of the Fellow commoners of Queen's College. In 1929 he was appointed honorary surgeon to H.M. King George V.

A keen officer of The Queen's Own Oxfordshire Hussars, Proudfoot served abroad during the war of 1914–18 as Major R.A.M.C. attached to this regiment. After being wounded in the second battle of Ypres he became O.C. 3rd Southern General Hospital and, later, A.D.M.S., 48th Division T.A., with the rank of colonel. At the outbreak of the present war he was chosen as the physician on the medical board for examining university and other candidates for commissions, and all who worked with him will testify to the happiness and good humour that pervaded the board. He had only recently taken on the presidency of No. 2 board in Oxford when it became obvious to his friends that he would not be spared to carry on.

In private life he was a most gracious host and a delightful companion. He was a fine judge of wine, and was perhaps at his best in the Common Room of his college after dinner. For many years he was a member of the Royal and Ancient Club of St. Andrews, and in his early days was a scratch golfer. Until only a short time before his death he would enjoy his round at Frilford Heath, where he had been captain. Dr. Proudfoot was a keen follower of university sports and was medical officer to the Oxford University Association Football Club and the Oxford University Boxing Club, as well as medical officer to the Oxford City Association Football Club. A lifelong Mason, he had the distinction of being a grand lodge officer and a past-master of the Churchill and Apollo Lodges. At the time of his death he was the Grand Superintendent of the Provincial Grand Chapter of Oxfordshire. When the British Medical Association met at Oxford in 1904 he was secretary of the Section of Obstetrics and Gynaecology, and at the meeting in 1936 he was vice-president of that section. Dr. Proudfoot leaves a widow and one son, who is serving as Lieut.-Commander in the Royal Navy. Those who have had the privilege of his friendship will miss his cheerful and breezy personality, which covered many acts of unadvertised kindness. His was a life well spent in the service of his profession and the State.

We record with regret the death of Dr. OWEN FOULKES EVANS, one of Liverpool's most well-known general practitioners. Dr. Evans qualified M.B., C.M. at Edinburgh in 1890 and took his M.D. of that University in 1894. Almost immediately after qualifying he began practice in Liverpool, where he was to remain for all his active medical life until failing health obliged him, very unwillingly, to retire in 1936. Keenly interested in the clinical rather than the scientific side of medicine, Evans soon gained a reputation as a good diagnostician. His examinations were always very thorough, and he did not hesitate to call in a specialist if in doubt. His patients were his absorbing interest; nothing he did for them was too much trouble. He was never in a hurry and never too busy to sympathize with them in their sorrows. His large practice allowed him little time for public or social work, but during his summer holidays he showed another side of his character in his complete enjoyment of a change of interests, of scenery, and of the many and varied entertainments which go to the making of a successful holiday. It was during these holidays that his deputies came into contact with his patients and realized their confidence in and affection for their "beloved physician." He had been a member of the British Medical Association for forty-five years.

Dr. ALGERNON DUTTON BRENCHLEY, who died at Bournemouth on December 5 at the age of 86, received his medical education at the University of Aberdeen and at Guy's Hospital, qualifying M.R.C.S., L.S.A. in 1875. He took the M.B., C.M. of Aberdeen in 1877 and three years later the M.D. of that university. He became a member of the Society of Apothecaries in 1876 and was Master of the Society in 1924–5. He was Senior Past Master and Father of the Court of Assistants at the time of his death. Dr. Brenchley had practised for many years at Denmark Hill, London.

We regret to record the death, at the age of 73, of Mr. THOMAS CAMPBELL GREY at Hexham on December 17. He was educated at the Bristol Medical School, receiving in 1889 the Committee Gold Medal of the Bristol General Hospital, and at the London Hospital. He took the Lady Haberfield Entrance Scholarship and the Martyn Memorial Scholarship in Pathology and was also a prizeman in medicine, midwifery, pathology, and anatomy. He qualified M.R.C.S., L.R.C.P. in 1890 and two years later took the F.R.C.S. He was assistant physician at the Bristol General Hospital and prosector and assistant demonstrator in anatomy and physiology at the Bristol Medical School. He then held the post of resident medical officer at Swansea Hospital and later went into practice at Weston-super-Mare, to which town he returned after a short period at St. Neots. He later moved to Camborne, being honorary medical officer to the local hospital and honorary surgeon to the Miners' Hospital, Redruth. He had been a member of the British Medical Association for thirty-six years and in 1903–4 was honorary secretary of the old Truro Division. In 1904 he moved to Corbridge-on-Tyne and three years later went to Basingstoke, where he was honorary medical officer to the cottage hospital, then to Wrexham in 1908, only to return to Hampshire, this time to Fordingbridge. In 1911 he moved to Cheltenham and then back to Corbridge-on-Tyne in 1915, and to Newcastle-upon-Tyne in 1921 until 1926, when he retired to Hexham.

We regret to announce the death, on December 24, of Dr. HELEN YOUNG CAMPBELL at St. Andrews. Dr. Campbell was the daughter of the late Mr. W. Y. Campbell of Durban, and took the Scottish triple qualification in 1907. She was for a time in practice in South Africa, where she wrote *Practical Motherhood* for mothers who lived in the remote

backveldt. On her return to England she worked at the Infants Hospital, Westminster, on problems of infant nutrition, and in 1911 was appointed medical officer to the Babies' Welcomes, which the Bradford Health Committee had recently taken over. She exhibited the intense and eager pioneer spirit and fearless courage needed to build from humble beginnings what became an outstanding piece of preventive medicine—the City of Bradford Infants' Department. Dr. Campbell worked untiringly at her conception of a clinic-hospital run by the city for the city, where the city's infants could be given a healthy start in life. She saw a scheme where that much-neglected group, the pre-school children, could be included and supervised up to their reaching school age. She would spend weeks of time studying and restudying the figures in her annual reports to see what fresh light they might throw on the problem of infant life and mortality. At various times she was offered work which would have given her wider scope in teaching, but all these she refused, saying that her work in Bradford was not yet completed. Her reward was the remarkable improvement in the health and physique of the children of Bradford and the reduction of the infant mortality rate. The continuation of the supervision of children until reaching school age, a development of maternity and child welfare work which she had much at heart, was not achieved in Bradford in her time. Her health did not stand the demands she made on it, time did not bring about the hoped-for improvement, and ultimately she resigned. She spent her retirement studying in the library of St. Andrews and writing, until latterly pain and infirmity kept her to her room.

We regret to announce the death of Dr. GODFREY CARTER formerly senior surgeon to the Sheffield City Police. Godfrey Carter qualified M.R.C.S. in 1880 and L.R.C.P.Ed. in 1884. In 1894 he took the M.R.C.P.Ed., and two years later the M.B., Ch.B.Vict. and the D.P.H.Lond. He was senior assistant house-surgeon at the Leeds General Infirmary, and demonstrator in anatomy and internal examiner in forensic medicine at Sheffield University. He was an external examiner in forensic medicine in the Universities of Leeds, Edinburgh, and Birmingham. Dr. Carter was for about twenty-five years in general practice in Sheffield. In 1923 he was president of the Medico-Chirurgical Society. For several years he held the post of surgeon to the Sheffield Police, and as such had a wide practical experience of forensic medicine, on which subject he was lecturer in the University. He was much interested in the detection of alcoholism by urinary analysis, a subject on which he published, in collaboration with Mr. Southgate, an article in this *Journal* in 1926. After leaving Sheffield he went to live in Somerset, where his forensic experience soon obtained for him the post of pathologist to the Taunton General Infirmary, and much medico-legal work over a wide district of the South-Western Counties. He was a vice-president of the Medico-Legal Society, and had been a member of the British Medical Association for fifty-three years.

We regret to announce the death on October 28 in his sixty-third year of Dr. JOHN BENJAMIN VALENTINE WATTS at Barberton, Transvaal. Dr. Watts was born at Durban, was educated at Maritzburg College, and studied medicine at Bristol, graduating M.B., B.S. of the University of London in 1906. He held the posts of casualty officer and junior house-surgeon at the Bristol Royal Infirmary, house-surgeon at Bristol General Hospital, and resident medical officer at Newport, Mon., Hospital, before, in May, 1907, he settled in practice in Barberton, Transvaal, where he gained a reputation as a surgeon. In 1925 he retired from practice for five years and then restarted practice in Cambridge, East London, retiring again early in 1939. He was a member of the British Medical Association and was chairman of the East London Division in 1935–6.

All those interested in international hygiene will learn with regret of the death in Paris on October 7 of CAMILLE BARRÈRE, Ambassador of France, Member of the Institute, and delegate for France on the Permanent Committee of the International Office of Public Health. It was to Barrère's inspiration and active support while Ambassador at Rome that the convention founding the International Office of Public Health was drawn up in 1907. He had been led early in his diplomatic career to take an interest in international hygiene, and had presided at four international conferences concerned with the Danube, Egypt, and the Suez Canal. He realized the importance, little recognized then but widely accepted now, of protecting commercial interests and preventing the spread of epidemics by a rational and uniform system of quarantine control throughout the world. Barrère represented France on the Permanent Committee of the Paris Office from its inception, and though he was often pressed to assume the presidency, his modesty always prevented him from doing so. He never intervened in technical discussions, but his advice and support were invaluable on questions concerning the organization and diplomatic status of the Office. In spite of advanced age and failing health he lost none of his interest in the work of the Office, nor any of his charm and courtesy to even the most junior delegate. To have known him was to realize why, of all French titles, that of "Ambassadeur de France" commanded the highest respect, and it could be wished that he had been spared seeing the end—as he saw the beginning—of the Third Republic.

The following well-known foreign medical men have died: LOUIS SPILLMANN, dean of the medical faculty of Nancy, aged 64; Dr. POUSSON, honorary professor of the Bordeaux medical faculty, aged 87; Dr. ROCAZ, honorary physician to the children's hospital at Bordeaux; Dr. GLENN E. CULLEN, professor of biochemistry in the University of Cincinnati; Dr. A. MCGLANNAN, emeritus professor of surgery at the University of Maryland School of Medicine, aged 67; Dr. HENRY CLARKE COE, emeritus professor of gynaecology at the New York University College of Medicine, aged 84; Prof. ABEL FILHO of Rio de Janeiro; Dr. PAUL PINTO ESCALIER of Buenos Aires; Dr. E. P. FIDANZA, professor of dermatology at Rosario, Argentina; Dr. ERNEST A. PRIBRAM, formerly professor of pathology in Vienna University, aged 61; Dr. ALEXANDER SWANSON BEGG, dean and Waterhouse professor of anatomy at the Boston University School of Medicine, aged 59; Dr. MAX ASCHNAZY, professor of morbid anatomy at Geneva; Dr. HECTOR CHRISTIAN, formerly professor of hygiene and bacteriology at the University of Geneva, aged 78; Dr. FRANCIS PARK LEWIS, co-editor of the *American Journal of Ophthalmology*, aged 85; Dr. CHARLES NICOLL BANCKER CAMAC, emeritus professor of internal medicine at the New York Polyclinic medical school and hospital, aged 72; and Dr. ARTHUR CARADOC MORGAN, associate editor of the *Pennsylvanian Medical Journal*, aged 70.

The Services

CASUALTIES IN THE MEDICAL SERVICES

ROYAL NAVY

Temporary Surgeon Lieut.-Commander JOHN BARCLAY BARR, R.N.V.R., whose death through enemy action is announced, was a graduate of the University of Glasgow, where he took the degrees of M.B., Ch.B. in March, 1936. For over two and a half years he was house-surgeon at the Western Infirmary, David Elder and Southern General Hospitals, Glasgow. He went on a voyage round the world as a ship surgeon, and his arrival at Port Said on the homeward trip coincided with the outbreak of war. He immediately returned home, and within a month of his arrival was appointed to one of His Majesty's ships. A native of Blantyre, he was educated at St. John's Grammar School, Hamilton, and at Biggar High School. He was a King's Scout. He joined the British Medical Association in 1936.

ROYAL ARMY MEDICAL CORPS

Lieut.-Colonel WILLIAM ARTHUR ROSEBERY SPONG died suddenly on December 22, 1940, at the age of 57, after a very short illness. He was born on April 11, 1883, and graduated M.B., Ch.B. at Trinity College, Dublin, in 1907. In the same year he entered the R.A.M.C. as lieutenant, being promoted major in 1919, lieutenant-colonel in 1931, and retiring in 1935. He did a long term of duty in India. During the war of 1914–18 he was for a time employed on embarkation and distribution duties in Karachi, and for his services was mentioned in dispatches. He was an Associate of the Order of the Hospital of St. John of Jerusalem in England. After retiring he settled in practice in Sutton Benger, Chippenham, and on the outbreak of the present war was appointed officer commanding a military hospital. He joined the British Medical Association

in 1910. Lieut.-Colonel R. H. L. writes: The many friends of W. A. Spong will hear with deep regret of his sudden death. He had spent many years of his Army service in India, and when he retired from active service a few years ago he settled in a busy country practice in Wiltshire, returning to serve on the outbreak of war. He was always a hard worker, never sparing himself either in doing his job or in looking after the welfare and comfort of those under his care, whether patients or personnel. He was generous to a fault, and it was his delight to know the Christian names of each child in his practice, chatting with them all in easy fashion, whether they came from the labourer's cottage or the mansion. A keen shot and angler both at home and abroad, he was happiest when he was able to snatch a few hours' respite to visit the banks of some river, full of anticipation, and, more often than not, reluctantly coming away with very satisfactory results. Our heartfelt sympathy goes out to his widow and children in their great bereavement

Lieut DAN BRADBURY died recently at his parents' home in Sheffield from shock when attempting to repair an electric light fault. He was educated at the University of Sheffield and graduated M.B., Ch.B. in 1939. He joined the British Medical Association in the same year.

Lieut. LOUIS HENDERSON MACDONALD is posted as "Died" in an Army casualty list published on January 6. He graduated M.B., Ch.B. at Birmingham University in 1924, and took the M.R.C.S., L.R.C.P. in the same year. He had been assistant medical officer to the venereal diseases department and house-surgeon and house-physician at the General Hospital, Birmingham, and assistant pathologist and bacteriologist at the Dudley Road Hospital, Birmingham. At the outbreak of war he was in practice at Southampton.

The name of Lieut. JAMES PATTINSON THYNE is included as "Killed" in an Army casualty list published on December 28. He received his medical education at King's College Hospital, and qualified M.R.C.S., L.R.C.P. in 1928. He had held the post of house-surgeon at the hospital, and before the outbreak of war was in practice at Wandsworth.

DEATHS IN THE SERVICES

Surgeon Rear-Admiral FREDERICK JOHN LILLY, R.N. (ret.), died suddenly at Hove on December 12, aged 82. He received his medical education at St. George's Hospital, and took the M.R.C.S. in 1882 and the L.R.C.P.Ed. in 1883. Entering the Royal Navy soon afterwards, he was promoted to fleet surgeon in 1900, became deputy surgeon general in 1907, and retired as surgeon general in 1912, this title being subsequently altered to surgeon rear-admiral. He had seen a lot of active service in various expeditions: in East Africa in 1892–3, when he was mentioned in dispatches and received the Africa General Service medal with a clasp; in the South African War of 1899–1902, as staff surgeon of H.M.S. *Forte*, he landed and served in the Naval Brigade in the relief of Ladysmith, and was present at the actions of Colenso, Spion Kop, Vaalkranz, Pieters Hill, and Elandslaagte, was mentioned in dispatches, and received the Queen's medal with two clasps; and as fleet surgeon of H.M.S. *Doris*, flagship, he served in the Gambia punitive expedition of 1901 and was mentioned in dispatches. He had been a member of the British Medical Association since 1884.

Colonel ALBERT GEORGE THOMPSON, C.M.G., D.S.O., late R.A.M.C., died at Redruth on December 11, aged 73. He was born at Islington on May 24, 1867, and was educated at the University of Edinburgh, where he graduated M.B., C.M. in 1891, also taking the D.P.H. of the Scottish Colleges in 1905. Entering the Army as surgeon lieutenant in 1892, he became lieutenant-colonel in 1915, received a brevet colonelcy in 1918, and retired in 1919. He served in the South African War in 1902 in the Orange River Colony, and received the Queen's medal with two clasps, and in the war of 1914–18, when he was five times mentioned in dispatches. He received the D.S.O. in 1917 and the C.M.G. in 1918. He also received the Médaille de la Reconnaissance Française. He had been a member of the British Medical Association for twenty-seven years.

Colonel SYDNEY GEORGE BUTLER, D.S.O., late R.A.M.C., died at Hove on December 29, 1940, aged 66. He was born on May 18, 1874, received his medical education at the London Hospital, and took the M.R.C.S., L.R.C.P. in 1897. After filling the post of house-surgeon at the Poplar Hospital he entered the R.A.M.C. as lieutenant in 1899, became lieutenant-colonel in 1915, and retired with the rank of colonel in 1920. He served in the South African War of 1899–1902, when he took part in the relief of Ladysmith, including the actions at Colenso, Spion Kop, Vaalkranz, Tugela Heights, and Pieters Hill, also in the operations in the Transvaal and in Cape Colony, and received the Queen's medal with five clasps and the King's medal with two clasps. He also served throughout the war of 1914–18, when he was twice mentioned in dispatches in 1914, in which year he received the D.S.O. From June, 1919, to January 1920, he was consulting surgeon to the British troops in France and Flanders, and in 1920–1 was consulting surgeon to the British Army on the Rhine. After retiring he served for a time as surgeon in the P. & O. Company. He had been a member of the British Medical Association for thirty-three years.

Colonel WILLIAM LECKIE WEBSTER, M.C., late R.A.M.C., died in London on December 1, aged 53. He was born on November 3, 1887, and was educated at the University of Edinburgh, where he graduated M.B., Ch.B. in 1910. He entered the R.A.M.C., from the Special Reserve, as lieutenant in 1911, received a brevet majority in 1919, and became full colonel in 1937. He had just been placed on retired pay on account of ill-health. He served in the war of 1914–18, was twice mentioned in dispatches in 1918, and received the M.C. as well as the medals. He leaves a widow. He had been a member of the British Medical Association for twenty years.

Medical News

In a statement made early this week Sir Wilson Jameson, Chief Medical Officer of the Ministry of Health, said that in the crowded deep shelters there were at present only stray cases of infectious diseases. He gave the following figures for the principal infectious diseases notified in 1938, 1939, and 1940 down to December 14: *Scarlet fever*: 1938, just over 99,000; 1939, just over 76,000; 1940, nearly 63,000. *Diphtheria*: 1938, 65,000; 1939, 46,700; 1940, just over 44,000. *Pneumonia*: 1938, 45,000; 1939, 42,000; 1940, nearly 46,000. *Dysentery*: 1938, 4,170; 1939, 963; 1940, 2,900. *Enteric fever*: 1938, 1,300; 1939, 1,500; 1940, 2,800. *Cerebrospinal fever*: 1938, 1,288; 1939, 1,500; 1940, approximately 12,500.

A meeting of the Pharmaceutical Society of Great Britain will be held at 17, Bloomsbury Square, W.C., on Thursday, January 16, at 2.30 p.m., when Mr. A. Mortimer will give an address on "Drug Supplies in Wartime."

The *Journal of the American Medical Association* announces that forty-eight physicians have formed a medical and surgical supply committee, with offices at 420, Lexington Avenue, New York, and undertaken a nation-wide campaign for surgical and medical supplies to equip 500 first-aid stations and field hospitals to help in caring for the British war wounded.

Dr. Charles Armstrong, senior surgeon of the United States Public Health Service, National Institute of Health, Washington, D.C., delivered the first Harvey Society Lecture of the current series at the New York Academy of Medicine on October 3, his subject being "Studies on Lymphocytic Choriomeningitis and Poliomyelitis."

Some members of the Pharmaceutical Society serving in the R.A.M.C. are at present in Iceland. They are faced with long winter nights when almost the only form of recreation is reading. Gifts of books—technical and fiction—would be very welcome and should be dispatched to Sergt. C. W. Vokins, R.A.M.C., Sergeants' Mess, 487 Field Ambulance, c/o Army Post Office 500.

The name of Dr. Donald Shrewsbury Todd-White has been brought to notice for brave conduct in connexion with civil defence.

The British Government has received a loan from Dr. J. V. Landor, physician and registrar of the General Hospital, Singapore, of £1,000 free of interest for the prosecution of the war.

An institute for endocrinology has been founded at São Paulo, Brazil, consisting of three departments devoted respectively to experimental endocrinology, human endocrinology, and a laboratory for testing opotherapeutic products.

Dr. Otto Loewi, for many years director of the faculty of pharmacology at Graz University, has been appointed research professor of pharmacology at New York University.

Medical Notes in Parliament

Protection of Practices in Bombed Areas

Mr. GROVES asked Mr. MacDonald on December 19 to consider formulating a scheme for the protection of panel practices of medical practitioners who had been injured or whose houses had been so damaged by enemy action that they were unable to continue for a time in practice. Mr. MACDONALD said he understood that insurance medical practitioners who suffered hardships by reason of air raids received every possible assistance from the Insurance Committees and their professional colleagues. Where his approval would be necessary to an extension of the Protection of Practices Scheme in operation in any area to cover practices in temporary abeyance as the result of air raids, he would be prepared to consider the matter on application from the Insurance Committee.

Notes in Brief

The recommendation of the Dental Benefit Council that there should be an increase in the scale of fees for the dental treatment of insured persons was rejected by the National Health Insurance Joint Committee on the ground that justification had not been shown for such an increase at the present time.

EPIDEMIOLOGICAL NOTES

Infectious Diseases for the Week

In England and Wales in the first week of December there were increases only in the incidence of pneumonia and whooping-cough as compared with the previous week. The fall in the incidence of measles, although probably only temporary, is gratifying. As regards the probability of an epidemic of influenza, factors difficult to assess with accuracy, such as the environment and nutrition of the population at risk, are probably more important than hypothetical alterations in the virulence or dispersal rate of the causative agent or supposed changes in the "epidemic constitution." The time is opportune for a controlled trial of the available antigens in influenza prophylaxis, but at present there are difficulties in the way of applying it on a scale sufficient to yield reliable results.

Registrar-General's Annual Report for Northern Ireland

There was a decrease of 502 births in 1939 compared with the previous year, the rate of 19.5 per 1,000 of the estimated population being 0.5 per 1,000 lower than in 1938. The rate for the aggregate of urban areas exceeded that for the rural areas, Londonderry C.B. showing the highest and Co. Fermanagh the lowest. Illegitimate births were 4.7 % of the total births registered, and were slightly in excess of the previous year. The death rate was 13.5 per 1,000, or 0.2 below the rate for 1938; with the exceptions of 1930 and 1934 this was the lowest rate recorded in the present century. In each successive quarter of the year equivalent death rates were: 16.5, 13.5, 11.4, and 12.8. The death rate for the aggregate of urban areas was lower than that for rural areas. Belfast C.B. recording the lowest and the counties of Londonderry and Tyrone, jointly, the highest. There were 1,779 deaths among infants under 1 year, or 70 per 1,000 births registered, compared with 75 in the previous year. In 1939 and 1938 the infant mortality rates for England and Wales were 50 and 53, for Scotland 68 and 70, and for Eire 66 and 67, respectively. The rates recorded in urban areas are generally considerably in excess of those in rural areas. The infant mortality rate among illegitimate children was 131, compared with 149 in the previous year; for legitimate children the rate was 68 and 72 per 1,000 respectively. Deaths from the principal epidemic diseases, except influenza and diarrhoeal diseases of children under 2 years of age, were fewer than in 1938. The decrease in the mortality from measles is marked, but only slight in respect of enteric fever, scarlet fever, whooping-cough, diphtheria, and dysentery.

No. 49

INFECTIOUS DISEASES AND VITAL STATISTICS

We print below a summary of Infectious Diseases and Vital Statistics in the British Isles during the week ended December 7, 1940.

Figures of Principal Notifiable Diseases for the week and those for the corresponding week last year, for: (a) England and Wales (London included), (b) London (administrative county), (c) Scotland, (d) Eire, (e) Northern Ireland.

Figures of Births and Deaths, and of Deaths recorded under each infectious disease, are for: (a) The 126 great towns in England and Wales (including London), (b) London (administrative county), (c) The 16 principal towns in Scotland, (d) The 13 principal towns in Eire, (e) The 10 principal towns in Northern Ireland.

A dash — denotes no cases; a blank space denotes disease not notifiable or no return available.

Disease	1940					1939 (Corresponding Week)

* Includes primary form in figures for England and Wales, London (administrative county), and Northern Ireland.

† Since January 1, 1940, figures for London (b) have been for deaths from all forms of pneumonia; the corresponding figures for 1939 relate to deaths from lobar pneumonia only.

‡ Notification in certain administrative areas only.

§ Death from puerperal sepsis.

Letters, Notes, and Answers

All communications in regard to editorial business should be addressed to THE EDITOR, BRITISH MEDICAL JOURNAL, B.M.A. HOUSE, TAVISTOCK SQUARE, W.C.1.

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* alone unless the contrary be stated.

Authors desiring REPRINTS of their articles must communicate with the Secretary, B.M.A. House, Tavistock Square, W.C.1, on receipt of proofs. Authors over-seas should indicate on MSS. if reprints are required, as proofs are not sent abroad.

ADVERTISEMENTS should be addressed to the Advertisement Manager (hours 9 a.m. to 5 p.m.). Orders for copies of the *Journal* and subscriptions should be addressed to the Secretary.

TELEPHONE NO.—B.M.A. and *B.M.J.*: EUSTON 2111.

TELEGRAPHIC ADDRESSES.—EDITOR, *Aitiology Westcent, London;* SECRETARY, *Mediscra Westcent, London.*

B.M.A. SCOTTISH OFFICE: 7, Drumsheugh Gardens, Edinburgh.

QUERIES AND ANSWERS

Dysmenorrhoea

Dr. J. E. O'LOGHLEN (Clapham Common) writes: "Country Practitioner" (December 28, p. 924) does not give sufficient details to make an exact diagnosis. Assuming that the gynaecological findings are negative, further interference in the way of examination or any kind of operation is not only contraindicated but might even be harmful; so also would be the application of antispasmodics such as belladonna, papaverin, codeine, etc. Endocrine therapy should only be prescribed when the diagnosis is confirmed. A good plan is to do a tolerance test of adrenaline, cocaine, and belladonna. This I was accustomed to do many years ago when working with Adler in Vienna. Might I also warn against the unnecessary dilatation and curetting operation? Adler did 1,400 in cases where the gynaecological findings were negative; less than 1% were relieved. Novak considers that more than 90% of cases are psychological. Oskar Frankl, with whom I was privileged to work, was of the same opinion, and would never agree with mechanical dysmenorrhoea, as is instanced by the large numbers of perfectly healthy women who have retroversions or anteflexions without discomfort until the condition is discovered accidentally. The age of the patient at the first menstruation, and its time, character, and duration, are of the utmost importance. Was it preceded by proper instruction in sex hygiene, or did haemorrhage appear suddenly, as in haemoptysis? Try and get a full family history, as well as details of occupation, hobbies, sports, and social contacts. Dysmenorrhoea may sometimes be allergic. Several cases have been described in America by Dudley Smith. Fifteen years ago I treated more than 600 cases of dysmenorrhoea by diathermy with excellent results. I thought then that the relief from pain was due to the diathermy, but have now come to the conclusion that it was mostly suggestion. Many of these cases are relieved by painting the inside of the nose both sides with a 5% solution of cocaine. The patient will of course not know what your magic drops are.

Dr. DUNCAN BALLANTINE (Rotherham) writes: May I suggest to "Country Practitioner" that he try the effect of benzedrine on his patient with dysmenorrhoea. I have now seen several patients who have been amazingly improved by this means, and certainly the price is far from exorbitant. The drug is said to be an antispasmodic to uterine muscle, and in addition gives the patient a marked feeling of well-being, in contrast to the usual depression. The dose suggested by the makers is two 5-mg. tablets taken immediately the symptoms arise, and if necessary repeated in four hours. It is as well to remember not to take the drug in the evening in case of insomnia, and it would be safer to test the patient's reaction by giving a smaller dose at some other time, as there are some people who have unpleasant effects following benzedrine.

A Case of Partial Impotence

"Q.R.S." writes: I wonder if any readers could give me information about a curious condition of semi-impotence which does not appear to fall into any of the more usual categories. For one year the patient has suffered from (*a*) diminished sensitivity to sexual excitement; (*b*) incomplete erections—that is, the corpora cavernosa penis erect strongly but the corpus cavernosum urethrae and glans hardly at all. A famous sexologist to whom the case was referred assured me it was purely functional in origin, but I am unconvinced. Up to a year ago the patient was strongly sexed and erections were complete. Is there any organic condition which would account for the specific distribution of the impotence?

Income Tax

New Partnership—Military Service

"T." purchased a share in a practice as from October, 1939, but did not acquire any book debts. In June, 1940, he joined the R.A.M.C., and pays into the partnership account his Army pay. A locumtenent has been engaged at £650 per annum. "T.'s" share of the partnership assessment for the year to April 5, 1941, is based upon the firm's profits for the year 1939; his cash receipts are of course much less than that amount.

*** It should be borne in mind that the liability is not calculated in such a case as this on cash receipts; "T." is liable for tax on his share of *earnings*, whether they have been paid to him or not. In the early years this does involve some financial hardship, but normally there is no escape from it. In the special circumstances, however, it is quite possible that relief can be obtained under Section 23 of the Finance Act, 1940. That section provides that where the earnings of the actual year fall short of the amount assessed by more than 20%, then the assessment shall be adjusted to the actual basis. We therefore advise "T." to write to the inspector of taxes intimating that a claim will be made under the above-mentioned provision when the necessary information is available. The inspector may properly ask for a payment on account to be made in the New Year if the facts are not ascertainable in the fairly near future.

LETTERS, NOTES, ETC.

Reflections on an Address to Medical Students

Dr. REDMOND ROCHE writes: In a vain wooing of sleep one night in "a safe area," where the enemy planes were making a noise, I was reading with much interest my friend Prof. Ryle's inspiring address to medical students of Cambridge at the customary opening of the session (November 16, p. 657), not, indeed, with the idea—far from it—that it would act as a soporific. As usual on such occasions, familiar to us all, a glowing picture was drawn, and rightly, of the hopes and aims that should animate the student and potential doctor. Just then—2 a.m.—in my doctor-host's house the 'phone sounded and the familiar night call was heard. I have never noticed this incident in the doctor's future, not by any means uncommon, mentioned in these addresses. Another reflection occurred to me on reading that ours "is almost the only scientific career remaining which is not concerned in some way with the destruction of life." Are there not among us, a few they may be, but enough to spoil the assertion—the advocates of euthanasia and the abortionists? And which of us, big or little, can look back and feel that by something he has done, or failed to do, a life has not been sacrificed? These remarks are doubtless hypercriticism. A pleasing set-off is the suggestion—not so usual in these addresses—of the splendid opportunities a student or doctor has, of which he should avail himself, for "developing a social conscience."

Medical Students for Shelters

Dr. E. M. H. HERBERT (London, W.1) writes: Having had an opportunity of observing the work done in some of the shelters and witnessing the activities of voluntary helpers and doctors, I think that unrivalled opportunities exist to give our younger colleagues a chance to study conditions under which the population is living. Why should not our medical schools detail some of their students to help in the posts and shelters? It would give them a wonderful chance to "study medicine in the raw," and also give them an understanding of social conditions. I think this is an ideal ground for learning general practice, besides being a great help to the community.

Gentian Violet in Stomatitis

Dr. RALPH JONES writes: Some time ago I sent a bad case of stomatitis in an adult to hospital, and was advised to try daily swabbing with a 1% solution of gentian violet. I gave this treatment a thorough trial with both children and adults, and found, like C. H. Smith and H. B. Johnson, who are quoted in your annotation (December 14, p. 838), that it never had the slightest effect.

Collodion Treatment of Herpes Zoster

Dr. CRANSTON WALKER (Birmingham) writes with reference to this subject (*Journal*, January 4, p. 38): Before covering the eruption with collodion it is advisable to be sure that secondary infection is not already established. Otherwise the patient is liable to return, or go elsewhere, with a new pain, local tenderness, malaise, and a raised temperature. Relief of these symptoms can be obtained by incising the covering of collodion and letting out the pus. No anaesthetic is required.

Corrigendum

The degrees of M.B., B.S. should have appeared after Lady Ruth Balfour's name in the New Year Honours list (January 4, p. 25).

SUPPLEMENT TO THE
BRITISH MEDICAL JOURNAL
LONDON SATURDAY JANUARY 11 1940

DIPHTHERIA IMMUNIZATION

The following is the text of a letter which has been sent by the Secretary of the British Medical Association to medical officers of health of county councils or sanitary authorities in England and Wales:

"A considerable number of medical officers of health have applied to the Association for a copy of the Association's scale for the remuneration of general practitioners undertaking diphtheria immunization. The Association's scale, together with a note of its application to typhoid inoculation, is given below:

(a) The method of immunization to be employed should be determined by the local authority, who should supply the necessary material without charge to the practitioner.

(b) The fee per injection of immunizing material should be not less than 2s. 6d.

(c) The local authority should determine whether anterior and/or posterior Schick tests are to be carried out. Where the services of general practitioners are utilized for this purpose a fee of not less than 5s. per Schick test, including the reading, should be paid.

(d) These fees are inclusive of a report to the local authority. The report should be as simple as possible, providing for the name of the patient, the date of the inoculation(s), the amount and name of the reagent used, the identification number of the reagent, and the result of the immunization.

(e) If immunization is undertaken on a sessional basis remuneration should be not less than 1½ guineas for a session of not more than two hours.

The British Medical Association suggests that the same scale—that is, sections (a), (b), (d), and (e)—should be adopted in regard to inoculation against typhoid where this is being carried out by general practitioners.

The Minister of Health has intimated that, in so far as his approval may be necessary, he is prepared to approve the Association's scale as set out above.

I am sure that medical officers of health generally will appreciate the importance of securing the co-operation of the general practitioners of their area in the performance of this important prophylactic work, even though it may be necessary, at least for the present, to organize this work on a sessional basis. The Minister concurs in this view, and, in order to remove any misunderstanding which may exist, is sending a further communication to this effect to local authorities."

DOSAGE AND PACKING OF A.P.T.

The Chief Medical Officer to the Ministry of Health has sent the following letter to all medical officers of health:

"The difficulty of obtaining large quantities of small glass ampoules has made necessary the use of rubber-capped bottles for the issue, through the Emergency Public Health Laboratories, of alum precipitated toxoid. It has come to my notice that this has caused some embarrassment both in districts where general practitioners have been employed in the past to perform the inoculations as well as in others where it is proposed to employ general practitioners for this purpose in the future. As the dosage of alum precipitated toxoid recommended (0.1 c.cm. and 0.3 c.cm.) is a very small one, it is obvious that each bottle contains a large number of doses of the prophylactic and is suitable for use only in the inoculation of considerable groups of children collected together in appropriate centres.

It is important that the support of the medical profession should be secured if the benefits of immunization are to be fully understood by the public, and I hope that the practitioners in your area will do everything in their power to bring these benefits to the notice of their patients.

General practitioners are well qualified to perform the inoculations, and if it is decided to use their services you should arrange for their attendance at centres on a sessional basis."

MEDICAL WAR RELIEF FUND

EIGHTH LIST

Previously Acknowledged—£11,694 1s. 1d. and £100 3½% Conversion Stock

Individual Subscriptions

£5 5s.—Dr. N. S. Gokhale, London; Dr. J. T. Ingram, Leeds; Dr. H. J. Starling, Norwich; Dr. A. T. Williams, Gold Coast.

BONUS OF OFFICERS OF LOCAL AUTHORITIES

Following representations by the British Medical Association, the Minister of Health has decided to withdraw his objection to the payment of cost of living bonuses to those officers of a local authority whose remuneration is subject to approval by him. After further consideration he has decided that he would not be justified in continuing to withhold his approval in the case of the particular officers concerned, where the proposal is to pay them the bonus being paid already to other employees of the same authority. He is accordingly prepared to sanction the payment of such bonus, during the period of its currency, to the officers referred to.

CAPITATION FEE OF POST OFFICE MEDICAL OFFICERS

The Post Office has agreed to raise the capitation fee of Post Office medical officers by 6d., this figure being comparable with the increase in the dispensing capitation fee recently awarded to dispensing insurance practitioners. It has further agreed to raise the fee for attendance on emergency or "itinerant" cases from 3s. to 3s. 6d.

Correspondence

Bush Nursing Hospitals

SIR,—Dr. W. Kent Hughes's, letter in the *Supplement* of August 31 (p. 20) is based on a misunderstanding. Four Bush Nursing Hospitals have been closed by reason of the absence of medical practitioners, and in three of these cases practitioners had worked for years and asked for the hospitals. The call of the city is overpowering, where there is no shortage. I am not aware of any offer being made to practitioners to accept a salary of £500 a year; but guarantees of £500, £600, and in one case £800 a year have been offered with the right to practise in addition; they have been, in general, unsuccessful.

The areas in which these hospitals are situated vary. In the Mallee the summer is hot, but the country is not treeless and the residents are fine, robust people. But for the moment two hospitals are in difficulties, though situated in nice townships and a country which reminds one of England—green, well watered, and prosperous. Yet in spite of these difficulties, greatly accentuated by the war, the Bush Nursing Hospitals continue to develop and now number fifty-eight. What is even more gratifying is that this co-operative system is extending to the outskirts of the city because of the superior accommodation, skilled nursing, and low charges. The maternal mortality in 18,623 cases is 2.2 per 1,000, really less, a fact which the women in the country appreciate.—I am, etc.,

JAMES W. BARRETT,
Honorary Secretary, Central Council, Victorian Bush Nursing Association.

Melbourne, Nov. 9.

WEEKLY POSTGRADUATE DIARY

FELLOWSHIP OF MEDICINE AND POSTGRADUATE MEDICAL ASSOCIATION, 1, Wimpole Street, W.—*Royal National Orthopaedic Hospital*, Stanmore.—Sat., 2.15 p.m. Final F.R.C.S. Clinical Orthopaedic Course. *Medical Society of London*, 11, Chandos Street, W.—Wed., Final F.R.C.S. Theoretical Orthopaedic Course. *Royal Cancer Hospital*, Fulham Road, S.W.—Daily, 9.30 a.m. to 1 p.m. Final F.R.C.S. Comprehensive Course; thrice weekly, 2 p.m. Final F.R.C.S. Operative Surgery Course.

TAVISTOCK CLINIC, Westfield College, Kidderpore Avenue, Hampstead, N.W.—*Sun.*, 3 p.m. Discussion: War Strain in Children: Its Manifestations and Treatment. To be opened by Miss A. T. Alcock.

DIARY OF SOCIETIES AND LECTURES

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—At Royal Society of Medicine, 1, Wimpole Street, W. Lectures by Prof. H. A. Harris: *Mon.*, 3 p.m., Growth in General; *Tues.*, 3 p.m., The Anatomy and Physiology of Locomotion and Posture; *Wed.*, 3 p.m., The Inherent Weakness of the Human Body, with Reference to Orthopaedic Practice.

ROYAL SOCIETY OF MEDICINE

Section of Therapeutics.—Tues., 2.30 p.m. Discussion: Active Immunization—Some Present-day Problems. Openers: Dr. H. J. Parish and Dr. I. H. Maclean.

Section of Dermatology.—Thurs., 2.15 p.m. Short paper by Prof. P. A. Buxton; Some Recent Work on the Louse. Discussion: Prevention and Treatment of Parasitic Diseases. Openers: Dr. H. MacCormac and Dr. A. M. H. Gray.

VACANCIES

EXAMINING FACTORY SURGEON.—The appointment at Lewisham (London) is vacant. Applications to the Chief Inspector of Factories, Cleland House, Page Street, S.W.1, by January 14.

BIRTHS, MARRIAGES, AND DEATHS

The charge for inserting announcements under this head is 10s. 6d. This amount should be forwarded with the notice, authenticated with the name and address of the sender, and should reach the Advertisement Manager not later than the first post Tuesday morning to ensure insertion in the current issue.

MARRIAGE

PEBERDY—LAWS.—On December 27, 1940, in Taunton, Geoffrey Robert Peberdy, M.D., D.P.M., Lieutenant, R.A.M.C., to Mary Laws, M.R.C.S., L.R.C.P.

DEATHS

CARROLL.—On January 4, 1941, at his residence, Prospect Villas, Church Lane, Harpurhey, Manchester, Patrick John Carroll, B.A., M.B., B.Ch., R.U.I.

KENNEDY O'BYRNE.—On December 30, 1940, at 15, Parklands Court, Hounslow West, Middlesex, John Moira Kennedy O'Byrne, L.R.C.P.S.I., in his sixty-first year.

TRENDS IN NUTRITION*

BY

SIR JOHN BOYD ORR, M.D., F.R.S.

The treatment of disease falls entirely within the sphere of the medical profession. There has consequently been little delay in applying the advances in our knowledge of nutrition to the treatment of deficiency diseases. But for the prevention of deficiency diseases we need a supply of protective foods sufficient for the needs of the whole population and at a price within the purchasing power of everybody. This involves economic and political problems which are regarded as being outside the sphere of medicine. There has for this reason been a greater delay in the prevention of deficiency diseases and the promotion of the higher standard of national health and physical fitness, which we now know can be attained by proper feeding, than in the advance of therapeutic dietetics.

Though progress has been slower in applying our new knowledge in preventive medicine a great deal has been attained in recent years by public health measures supplying milk, cod-liver oil, and other protective foods, free or at a cheap price, at child welfare centres, ante-natal clinics, and schools. These measures have helped to prevent the grosser forms of deficiency diseases among mothers and children of the poorer classes. One of the best features of this public health work is the closer supervision of health, with the earlier detection and treatment of diseases due to faulty diet.

In the present circumstances, when the whole nation is putting forth its maximum effort for victory, it is of the utmost importance that the entire population should receive a diet which will maintain the highest degree of health and fitness that can be attained by proper feeding. It is difficult to do this under war conditions. The valuable public health work which was rapidly eliminating the worst forms of deficiency diseases among the poor is liable to be to some extent dislocated, and the supply of certain of the more important protective foods, such as eggs and imported fruits, is decreasing. The newer knowledge of nutrition which is of practical value must be brought to bear upon the problem to enable us to get through the difficult war and post-war period not only without a worsening of the national diet but, if possible, with an acceleration of the rate of improvement in recent years.

This raises the question of what knowledge is of practical value. The science of nutrition has been advancing so rapidly that there is difficulty in judging what has been definitely established. There is much room for differences of opinion. In the leisurely times of peace, discussion and dispute, followed by further investigations to clear up the points in dispute, form a normal and natural aspect of research effort. Under the present hectic conditions there is no time for discussion on minor points. We must take the information that is regarded by the majority of the profession as established and concentrate our efforts on getting it applied. It is of interest, therefore, to consider what knowledge can be regarded as of immediate practical value. The main questions are: To what extent does malnutrition exist or, in other words, to what extent could national health be improved by better feeding? What are the effects of malnutrition on national health and physique? In what respects are diets deficient and how can the deficiencies be made good from the food resources available? And, lastly: What bearing has the new knowledge of nutrition upon the national effort for victory and upon schemes for post-war reconstruction?

The Extent of Malnutrition

It is generally agreed that "deficiency diseases" are due to faulty diet. But there must obviously be many gradations of ill-health, from the highest state of health, which can be attained by perfect feeding, to conditions so gross that they are referred to as diseases. There is not complete agreement on the extent to which intermediate stages of deficiency diseases account for the rather vague and indefinite ill-health which is so prevalent. Attempts have been made to estimate this by various means, but we are not unanimous as to the validity of the methods of assessment of the state of nutrition used nor of the findings obtained by these methods. It will be of interest to consider these and see what can be regarded as being generally accepted.

Methods of assessing the State of Nutrition

Physiological and Chemical Tests.—Tests such as the hemeralopia test for deficiency of vitamin A, and chemical examination of body fluids to determine the phosphatase level or the degree of saturation with various vitamins and minerals, are giving interesting results. But the significance of certain of these tests is still in dispute. For example, some workers cannot find a close correlation between the results of hemeralopia tests and the intake of vitamin A or between the results of these tests and clinical signs of deficiency of this vitamin, and not all workers are agreed that saturation with ascorbic acid is necessary for perfect health. The increase of knowledge may bring about modifications in these tests and in the standards by which the results are judged. The principles on which such tests are based and sound and in the near future

* Summary of a British Medical Association Lecture delivered to the Leeds Division on November 12, 1940.

they will be generally accepted as valid. Those who have been carrying out research in this field, such as Harris and his co-workers at Cambridge, have done invaluable work. At the present stage, however, all that can be said with certainty about the results is that they indicate that the diet of a large proportion of the people in this country is not up to the optimum, and that in some cases it is so deficient that clinical signs of deficiency might be expected.

Clinical Assessment.—Clinical assessment presents difficulties because in minor degrees of deficiency there are few clear-cut clinical signs or symptoms which arise from specific deficiencies and from no other cause. Thus, for example, in minor degrees of deficiency of vitamin B_1 there is loss of appetite and there may be vague aches and pains of a rheumatic character, cardiac and intestinal derangements, and mental symptoms. All these, however, may arise from psychological or material causes other than deficiency of B_1. The same applies to a large extent to signs of deficiency of other vitamins or minerals. Clinical signs which are easily distinguished and characteristic of specific deficiencies occur only in the later stages of deficiency diseases and therefore are of limited value in estimating the extent to which minor degrees of malnutrition occur. When, however, a more detailed examination is made—as, for example, by *x* rays for rickets and estimation of haemoglobin for anaemia—many cases of subacute malnutrition are seen to exist in children who show no gross signs of ill-health.

In the past the clinical training of the medical student has not made him well fitted to recognize minor degrees of malnutrition. The clinical material for his training consisted of hospital patients who were nearly all in a rather advanced state of ill-health, and the student was too apt to classify the population into two categories—those so ill that they required medical treatment, and the rest of the population not seeking medical treatment, the average health of which was regarded as the normal. This standard of health is far below what we now regard as attainable. In some schools physiological and clinical teaching has begun with subjects of perfect health and physique with the idea of imparting a proper standard of health.

Dietary Surveys.—An estimate of the extent of malnutrition can be got by comparing the kind of diet in common use in different classes with the modern standard of requirements. If these standards be correct, then it may be assumed that the people on diets markedly below these standards are likely to suffer from malnutrition. There are three well-known standards—the British Medical Association diet at minimum cost; the "Stiebeling" diet at moderate cost, published by the U.S.A. Government Department of Home Economics; and the League of Nations diet, which is an optimum one irrespective of cost. Crawford has converted the B.M.A. diets into their nutrient constituents, allowance being made in accordance with the B.M.A. recommendation for one pint of milk daily for children from birth to 5 years, half a pint from 5 to 10, and a quarter of a pint for other persons. When the three diets are reduced to their nutrient constituents it is found that there is close agreement between them, the Stiebeling diet at moderate cost being a little more generous than the B.M.A. diet at minimum cost, and the League of Nations optimum diet a little better than the Stiebeling one. These standards were drawn up independently by different groups of experts, and can be accepted as fairly reliable indications of requirements. When diets in common use are compared with these standards it is found that the average intake of some minerals and most of the vitamins among poor families with children is low.

Feeding Tests.—If we accept as our definition of malnutrition a condition which can be improved by improving the diet, then the surest method of estimating malnutrition is to do feeding tests. The results of tests such as those in which additional milk was given to school children, and the experiment with the modified Oslo breakfast done by Borland in 1938, show that the average degree of health, which is often taken as the normal, can definitely be improved in a large proportion of these children. The marked improvement in health and physique of young recruits on joining the Army is undoubtedly largely due to better feeding.

In the last twenty-five years the average consumption of protective foods in this country has increased by roughly about 50%, and there has been a corresponding remarkable improvement in national health, shown by the great reduction in deficiency diseases due entirely to better feeding, by the reduction in infant mortality rates and tuberculosis death rates, and by the improvement in health and rate of growth of children, which can be attributed largely to the same cause. Although there has been such an improvement the results of recent tests indicate that we have not yet reached the limits, or, in other words, there is still ill-health and poor physique which could be eliminated by dietary measures.

All these different methods of assessing the state of nutrition show the same general results. Physiological and biochemical tests indicate that the diet of a large proportion of our children is not up to the optimum. Clinical examinations, such as that made by the Board of Education on rickets in London and Dr. Spence's examination of Newcastle pre-school children, disclose a considerable amount of malnutrition. A comparison of the diets in use with recognized standards shows that large numbers of the population do not receive a diet up to the standards which we now regard as being necessary for health; and, finally, feeding tests with children reveal that improvement of the diet is followed by a corresponding improvement in health. Even allowing for the fact that none of these methods of assessment is absolutely reliable, there can be little doubt about the conclusion, since the same general result is obtained independently by each method. The time is not opportune for discussing what proportion of the population is below the standard of health which we now know can be attained by proper feeding. It is sufficient for our purpose if there is general agreement that there are substantial numbers whose health and physique can be improved.

Effects of Malnutrition: Primary

The primary effects of malnutrition as seen in the deficiency diseases are well known. Only one—the effect on working efficiency, which is of special importance at the present time—need be referred to here. The improvement of the diet of workmen whose diet was not previously up to the standard for health is followed by increased output without any conscious increased effort and also by a reduction in the number of accidents. Many factories are now providing a meal for employees. It is likely that, as part of the national effort for increased output of war material, the provision of a meal will be made compulsory in all factories and measures be taken to ensure that the meal is on the lines of the Oslo breakfast, which will make good the deficiencies of the portion of the diet eaten at home.

Secondary

(*a*) *Infection.*—It is only in recent years that systematic research has been done on the influence of nutrition on susceptibility to infectious disease. About fifteen years ago the subject was investigated by a group of workers

associated with the Rowett Institute, including Prof. Mackie of Edinburgh and the late Prof. J. J. R. McLeod. In experiments with farm animals it was found that certain immunological reactions were considerably affected by the nature of the ration. In direct feeding experiments with rats, in which an infection was introduced into groups of the animals fed differently, it was found that with some infections, though not all, the mortality rate among those on a deficient diet was markedly higher than among those on an adequate diet. The results of these tests are complicated by acquired immunity. It is exceedingly difficult to get large groups of animals completely free from any previous infection which may complicate the results. That condition, however, has been obtained in Professor Topley's department at the London School of Hygiene and Tropical Medicine. His workers found that susceptibility to some infections is affected by diet. Thus, for example, well-fed mice are less susceptible to enteric than comparable animals on a poor diet.

These researches confirm clinical findings such as the increased susceptibility to infections of the cornea in deficiency of vitamin A, the frequent occurrence of bronchopneumonia in children suffering from rickets, and the effect of feeding on tuberculosis. While our knowledge of the effect of diet on immunity to infection is still very limited there can be little doubt that well-fed people are less susceptible to some infections, at least, than ill-fed people, and that the sequelae to many infections such as measles are likely to be more severe in children on a deficient diet.

This is a subject of considerable importance at the present time, when there is a displacement of the population. Endemic diseases in communities which have acquired immunity are apt to be spread to other sections of the population with little or no immunity. In addition to sanitary methods, and widespread immunization in the case of diseases where this method can be effectively employed, there is urgent need to increase the resistance of the people by improving their state of nutrition.

(*b*) *Psychological.*—An aspect of this subject which has so far received little attention is the psychological effect of malnutrition. This is especially marked in those suffering from pellagra, a proportion of whom end up in asylums. Vitamin B_1 deficiency in adults is accompanied by apathy and despondency, and in infants a typical symptom is the whining, whimpering, pathetic cry. A low blood calcium is accompanied by hyperexcitability. Women suffering from nutrition anaemia are usually apathetic, peevish, and easily discouraged. It is doubtful whether there is any physical symptom of malnutrition which is not accompanied by a psychological symptom.

This aspect of malnutrition is now receiving a good deal of attention by educationists. The number of dull or backward children, according to Segar, varies from about 1% among well-to-do families to 20% amongst the poorest families. Many intelligence tests have been used in an attempt to ascertain whether there is a correlation between nutrition and intelligence. As mental ability is an inherited characteristic it is doubtful whether the results of such tests, from one point of view, are of much value. The power to use intelligence, however, depends upon the state of health. A badly fed child suffers from early onset of fatigue and lack of power of concentration, and consequently is slower to learn. In some tests it has been found that supplementary feeding of milk and other protective foods has been followed by a definite improvement in the ability of the child to learn lessons. In a test which covered a period of five months the educational advance in that period was equivalent to the advance normally made by these children in two years. It is estimated that out of between five and six million school children five hundred thousand are dull or backward. While it may be going too far to label these children not mentally deficient but nutritionally deficient, as has been done by one American investigator, there seems little doubt that the number would be drastically reduced if their diets were made adequate. There is some apprehension at the wartime interference with the education of our children. If means were taken to ensure that every child was properly fed it is probable that the interference with the normal educational machine would be compensated for by the greater physical and mental vigour of the children.

In the present circumstances, when all sections of the community are being subjected to the emotional strains of war conditions, this aspect of nutrition assumes great national importance, both for adults, whose working efficiency and morale must be maintained at the highest possible level, and for the children, who when they grow up will need all their physical and mental powers to clear away the wreckage of the present war and build the new and better post-war world for which we are all hoping.

Characteristics of Deficient Diets

So much work has been done and so much written about the effects of deficiencies of the different vitamins or minerals that we are apt to think that improvement of the diet consists in making good these individual deficiencies. In the treatment of gross deficiency diseases vitamin concentrates are useful. They are of less value, however, in dealing with minor degrees of malnutrition, because poor diets are deficient not in one but in many constituents, and if the intake of one be increased the intake of some other immediately becomes the limiting factor for health. What we are dealing with is not diets deficient in one or two constituents but diets deficient in many. In tests the improvement got by giving one nutrient, such as vitamin A, is negligible compared with the improvement obtained by giving milk, which is rich in most of the elements deficient in a poor diet. This is well exemplified in the case of teeth. Deficiencies of vitamins D, A, and C, of calcium, and of magnesium; the effect of carbohydrates in promoting the growth of *B. acidophilus odontolyticus*, which attacks the enamel: mechanical chewing, which affects the growth of the jaws and the tooth-spacing, all help to determine the condition of the teeth. But the correction of any one of these factors will not ensure healthy teeth. Schiötz found in his extensive investigations that of children who had perfect teeth some had had cod-liver oil, some had not; some had been given sweets, some had been kept off sweets; some had brushed their teeth and some had not. But every child who had perfect teeth had had an abundance of milk and green vegetables regularly, without a break. These together supply all the known factors needed for healthy teeth, and possibly also as yet unknown factors. It has been decided to put vitamin B_1 and calcium into white bread. This will certainly to some extent improve diets deficient in these substances, but Harriette Chick's experiments have shown that white bread plus B_1 and calcium is by no means equivalent to wholemeal bread, which contains, in addition to these factors, several others which are equally important.

In planning for a perfect diet we should depend not so much on attempts to provide a sufficient amount of any specific nutrient as on ensuring that the intake of the protective foods is ample. We do not yet know all the dietary constituents which are essential for health, but we do know that a sufficiency of the protective foods will supply everything which the body needs. Fortunately,

everything can be supplied by a few foods—e.g., milk, green vegetables, wholemeal bread, and potatoes. These, taken together in sufficient quantity, would meet all bodily needs for specific constituents.

This is of importance at the present time, when the supply of some of our foods, such as eggs and imported fruit, will be reduced. This country can produce enough milk, vegetables, and potatoes to meet the needs of the whole population, and there is no insurmountable difficulty in making wholemeal bread available. The change over to increased consumption of these protective foods will involve an alteration in dietary habits. The chief change needed for health is to bring the consumption of milk and vegetables among the poor up to what it is among the well-to-do. At a time when all classes are prepared to make sacrifices there should be no difficulty in getting people so to adjust their diets as to increase the consumption of those foodstuffs which can be made available in sufficient amounts, especially as the main feature of the adjustment would be a levelling up of the diet of the poor by increased consumption of protective foods which we can produce at home, and the limitation, without necessary deterioration, of the diet of the well-to-do by reduced consumption of less essential foods.

Even though our agricultural policy were adjusted to provide milk, vegetables, and potatoes in amounts sufficient for the whole population there remains the problem of making them available at a price within the purchasing power of everybody. The Ministry of Food is engaged on a great educational campaign on the nature of body-building foods, protective foods, and energy-yielding foods. The value of this campaign would be greatly increased if specimen diets were given for families with three, four, or five children, and the price of the food stated, showing that families of low-wage earners, unemployed, and men in the Fighting Services could purchase these diets with the income available for food. The Canadian Medical Association has published an excellent booklet showing the kind of diet needed for different families and the cost, and has thereby adjusted propaganda to economic realities.

Nutrition only One Factor needed for Health

Such spectacular results have been obtained in the treatment and prevention of disease by dietary measures that there may be a danger, especially on the part of those working on the subject, of forgetting the importance of other factors. Bad housing and overcrowding, which facilitate the spread of infectious disease; the psychological effects of overcrowding; and the feeling of frustration, worry, and anxiety, and of impotence in the face of environmental difficulties common among the poor, are probably as potent causes of ill-health as faulty diet. These factors will react on one another and reinforce each other. Until they have been eliminated we will not be able to attain the high standard of national health and physical fitness which we know can be attained. They all tend to be associated with poverty.

In the last hundred years the medical profession has developed great resources for the treatment of diseases arising under these conditions. It is now recognized that the duties and responsibilities of the profession must be extended to include the prevention of disease and, further, the promotion of health. When we enter this sphere we are faced with the environmental conditions which affect health and with the associated social, economic, and political factors. The Report of the British Medical Association Committee on Nutrition, and the "Aylesbury Broadside," published by the *Lancet*, show that the profession has the vision and the courage to take cognizance of these factors. The profession must extend its work in this new sphere if it is to play a part commensurate with its great influence and prestige in building up the new and better world for which all men are hoping.

Medicine and the New World Order

The different ideologies which are in conflict promise a new world order. In our own country Mr. Bevin has said that after the war the miseries of poverty will be relegated to the limbo of the past, and Mr. Churchill has declared that we shall go forward in "the march of the common people towards their just and true inheritance and towards the broader and fuller life." Groups of economists and others are already planning, and indeed the Government has recently set up a special department to work out schemes for post-war development.

But we cannot with safety leave the planning of the future to political parties. As the *Times* in a leading article on a speech of President Roosevelt's says, "The gravest danger to democracy lay in the growth in some quarters of a cynical belief that the attitude to the all-important party machines was determined less by the voters than by the economic interests of those who provided the party funds." Nor can we leave it to the economist, who is too apt to think that prosperity consists of a trade boom. The miseries of the slums and the poverty created during the tremendous industrial and trade prosperity of the nineteenth century have convinced all thinking people that trade prosperity and the welfare of the working classes are not necessarily correlated. We must plan for the satisfaction of human needs as well as for trade prosperity.

The medical profession contains within it experts on every subject that affects human welfare. It is the only organized group of men competent to make a statement on human needs. The first essential need for a fuller life for the common people is the provision of environmental conditions which will enable them to attain their fullest inherited capacity for physiological and mental well-being. The British Medical Association might well set up a committee to report on the minimum material and psychological needs for full physiological and mental well-being. It could then, with the authority of the whole profession, recommend that in post-war planning effort should be directed first and foremost to the satisfaction of those needs for the whole population.

Some needs, such as better housing, cannot be dealt with during the war, but others, such as the provision of an adequate diet for everybody, could be met even during the war if we had an agricultural and food policy based solely on the nutritional requirements of the people. If this, the most fundamental need, were met, at the end of the war, even though we were poorer in other respects, we would have taken the first and most important step in the march of the common people to the fuller life, and the provision of plans for meeting other needs would give enthusiasm to continue the march and also confidence that we were travelling in the right direction.

Unfortunately, in the past, as Dr. R. W. L. Ward has pointed out in a recent letter to the *Journal*, the profession has been too much occupied with its own remuneration and failed to recognize its responsibilities towards the bigger issues of national life. At the present time, when the artisan trade unions are surrendering rights and privileges which have been won after such arduous struggles and are throwing the whole weight of their influence into the prosecution of the war in the hope of obtaining a new and better order, the medical profession must do its utmost to ensure that the better order which will compensate for all the sacrifices of the war will in fact materialize. It should assume that it is the custodian of

the health of the people and that it is its duty to define the environmental conditions necessary for the higher state of health which medical science considers can be attained. There is not the slightest doubt that the brave words of Churchill and Bevin are spoken in earnest and that they and other national leaders who are anxious to reorganize our social and economic system for the benefit of the common people would welcome an authoritative statement from the medical profession on the kind of conditions we should plan for. If the profession is willing to make its full contribution to the national effort for victory and for the equally important post-war reconstruction it should begin to do so now.

A CASE OF PULMONARY CONCUSSION ("BLAST") DUE TO HIGH EXPLOSIVE

BY

GEOFFREY HADFIELD, M.D., F.R.C.P.
Professor of Pathology, St. Bartholomew's Hospital

AND

RONALD V. CHRISTIE, M.Sc., M.D., M.R.C.P.
Professor of Medicine, St. Bartholomew's Hospital

It is now well recognized that a proportion of individuals who are exposed to the detonation of high explosive develop pulmonary haemorrhages without any significant injury to the thoracic wall. The number of recorded cases in which such patients have been closely observed and have subsequently died is still quite small. Such a case is recorded below.

Case Report

In November, 1940, a bomb fell on a wooden hut in which the patient, a soldier aged 23, was asleep. No details are available of the immediate effects of the explosion or of the condition of the patient at this time except that he was given morphine 1/4 grain at 4.40 and 1/3 grain at 5.20 and 3,000 units of anti-tetanus serum at 5.30, when he was transferred to hospital.

On admission he was "shocked," dyspnoeic, and cyanosed, and rales could be heard scattered throughout the chest. He had pain in the chest and abdomen and vomited some blood-stained fluid. The abdomen was tender and rigid. The temperature was 100°, and the pulse rate 130 and the respiratory rate 30 per minute. He was given heroin grain 1/12 and atropine grain 1/100, and oxygen was administered. His condition gradually improved. On the morning after admission tubular breathing with an impaired percussion note was found at the left base, but the scattered rales were less conspicuous. A radiograph of the chest showed a diffuse, mottled, woolly shadow throughout the left lung. On the right side there was a similar shadow in the mid-zone and extending out to the periphery from the hilus. The abdomen was still tender and vomiting continued. The temperature was 98.6°, and the pulse rate 120 and the respiratory rate 24 per minute.

It was decided in consultation that the patient should be sent to another hospital, and he was first seen by us thirty-nine hours after the explosion. He was restless and looked ill with high colour and slight cyanosis. There was considerable dyspnoea, with dilatation of the alae nasi on inspiration, but no orthopnoea. He was extremely irritable and resentful of interference, drinking greedily but vomiting large amounts of thin brownish watery fluid which gave a faintly positive guaiacum reaction. His temperature was 99.6°; the pulse rate was 120 and respirations 36 per minute. The tongue was dry and furred. Blood pressure was 126/76. There was generalized tenderness, which made accurate percussion and examination of the back of the chest inadvisable. Movement was diminished on the left side and the breath sounds were obscured by loud rhonchi and scattered coarse rales. The abdomen was distended with flatus and the abdominal wall was rigid and tender. An acute intra-abdominal lesion was suspected, although there was no dullness in the flanks, the liver dullness was not impaired, and bowel sounds were audible. Attempts were made to administer oxygen by means of a B.L.B. mask and spectacle frame, but the patient resisted and would tolerate neither. At 8.30 p.m. his general condition appeared unchanged, although the pulse rate had risen to 140 per minute and there was some congestion of the veins in the neck. His blood pressure was 136/84 and the haemoglobin 125% (Hellige colorimeter).

At this time the indications for treatment seemed somewhat confusing. The furred and dry tongue, the haemoglobin percentage of 125, and the rapid rate of the pulse suggested that plasma should be given. On the other hand, the height of the blood pressure, the distended veins in the neck, the bubbling rales in the chest, and the general appearance of the patient strongly suggested that a venesection should be performed. We decided to do neither, hoping this was a transient crisis precipitated by the journey from the first hospital. As the patient was quiet if left undisturbed, morphine was withheld and he was closely watched. At 11 p.m. it was obvious that his condition was deteriorating. He developed a distressing hiccup, the bubbling rales in his chest could be heard at the end of the bed, his cyanosis was increasing, and the veins in his neck were distended up to the angle of the jaw. The temperature was 102.2°, the pulse rate 144, and the respiration 48. Morphine grain 1/6 was given, but the condition of the patient began to deteriorate even more rapidly. 600 c.cm. of blood was then withdrawn, and this was followed by spectacular improvement. The bubbling rales in the chest rapidly diminished; the patient was quieter, was less restless, and was breathing more easily, and he fell into a light sleep. His blood pressure was not measured lest it disturb him, but the quality of his pulse suggested that it was being maintained at its previous level.

At 5.30 a.m. the patient became much worse and was restless and delirious. The rate of the pulse was 140 per minute, and its volume was poor; there was a systolic blood pressure of 44 mm. Hg, but no congestion of the veins in the neck. The respiratory rate again increased to 40 per minute, but no rales could be heard in the chest anteriorly except in the left axilla. The haemoglobin was 100%. Oxygen was administered with a B.L.B. mask and, as no plasma was immediately available, a transfusion of blood was begun. After the patient had received one-third of a pint clotting occurred. He was then moribund, and died at 7 a.m.

In a sample of blood taken at 11 p.m. the blood urea was 86 mg. per 100 c.cm. and the alkali reserve 60.5 c.cm. per 100 c.cm. plasma.

Post-mortem Examination

The body showed no external signs of injury except a small superficial abrasion on the bridge of the nose. The upper air passages were normal except that they contained a moderate amount of lightly blood-stained thin and frothy mucous fluid. The pericardial fluid was lightly blood-tinged. There were some petechial haemorrhages between the parietal pleura and the thoracic wall and a few larger haemorrhagic areas up to the diameter of a five-shilling piece in size. These were composed of thin laminae of dark blood and were not associated with any recognizable fracture of the ribs or trauma of the thoracic parietes. There was no excess of fluid in the pleural sacs.

Both lungs were large. At least two-thirds of the bulk of the left and about half the bulk of the right lung were consolidated. The visceral pleura showed no laceration, but there were several extensive dark irregular haemorrhagic areas beneath the pleura of both lungs, chiefly disposed about the posterior and basal regions; the largest was roughly rectangular, and measured about 6 by 5 cm. All these lesions were subsequently shown to be continuous, with large foci of deeply seated resolving haemorrhage.

Most of the consolidation in the left lung was basal, posterior, and deeply placed, but there were solid areas deep in

the substance of the upper lobe. The colour of the consolidated parts was that of dark venous blood clot, but their ill-defined edges were bright red, fading off gradually into normally coloured lung. Throughout this dark-coloured consolidated lung there were many scattered areas of ashen-grey in colour and sharply demarcated from the surrounding tissues. The larger areas were about 2 by 1½ cm.; and were roughly polygonal in shape. The light red margins of the consolidated areas were firm and elastic; the deeply coloured solid lung was wooden in consistency and quite elastic; the ashen-grey foci were firm but friable.

The lesions in the right lung were similar to those in the left but not so extensive, and whereas a large portion of the left lower lobe appeared to be occupied by a lesion roughly resembling a massive organizing pulmonary infarct, the lesions in the right lung were smaller and more widely scattered. The sharp demarcation of the ashen-grey areas was just as noticeable in the right as in the left lung.

A few small submucous haemorrhages were found in the body of the stomach and there were recent symmetrical subarachnoid haemorrhages over the convexity of each occipital lobe extending forwards for about 4 cm. from each occipital pole. These haemorrhages were not severe in degree and there was no naked-eye evidence of damage either to the overlying skull and dura or to the underlying brain.

On histological examination of the consolidated lungs the macroscopic changes were seen to be largely the consequence of widespread intra-alveolar capillary haemorrhage. In the dark firm elastic areas the appearances bore a striking resemblance to those found in haemorrhagic infarction. There was the same preservation of the outline and structure of the alveolar walls, the same tight packing of the alveoli with partly haemolysed and rather poorly staining red cells, and the same lack of free tracking of blood through the substance of the lung. There was no microscopic or macroscopic evidence of tracking of air through the lung, as one might expect to find if there had been alveolar rupture of any degree. The general resemblance to infarction and the lack of convincing evidence of widespread alveolar rupture incline us to the belief that the haemorrhage in this case arose from diapedesis or from the rupture of grossly dilated capillary vessels. This view receives some confirmation from the fact that a considerable degree of generalized capillary dilatation was found in sections taken from air-containing parts of the lung unaffected by haemorrhage.

No striking or constant change was observed in the air-conducting system of the lung, but in all sections of the regions showing haemorrhagic consolidation there was a rather striking degree of dilatation of the respiratory bronchioles and alveolar ducts.

An unexpected and rather surprising histological picture was presented by the ashen-grey friable areas lying in the midst of the massive areas of haemorrhagic consolidation. Here every alveolus contained a precisely staining close-meshed fibrin network in the meshes of which considerable numbers of wandering cells and partly haemolysed red cells were lying. The general appearance under the low-power bore a rather striking superficial resemblance to that of lobar pneumonia in the stage of red hepatization.

Closer examination of the wandering cells showed them to be predominantly monocytic. The capillaries in the alveolar walls were considerably dilated, and towards the edges of these areas of pseudo-pneumonic consolidation more and more alveoli were seen to contain coagulated protein with a scantier fibrin network and fewer cells. There was the same general preservation of the alveolar walls in these areas as was found in the frankly haemorrhagic parts of the lung and the same degree of dilatation of the respiratory bronchioles and alveolar ducts.

These appearances bear more than a superficial resemblance to those found in the lung in those cases of rheumatic infection dying of acute cardiac failure which show the condition known as "rheumatic pneumonia."

Sections taken from the peripheral parts of the areas of haemorrhagic consolidation where the lung was firm and airless but bright red in colour showed all alveoli in these areas to be fairly tightly packed with fresh, well-staining, fully haemoglobinized red cells. Wandering cells were absent and there was no fibrin formation. The alveolar walls were for the most part intact.

Discussion

The changes seen in these peripheral areas bore a striking resemblance to the appearances found in the lungs of patients dying soon after exposure to the detonation of high explosive, in which cases recent pulmonary haemorrhages are so often found post mortem. In reviewing a series of post-mortem examinations of seventeen of these cases we have been struck by the variability in extent of these haemorrhages, and it appears reasonable to relate this variation to the period of survival after exposure to detonation. In the case here described the survival period was longer than in any case we have previously observed and the haemorrhagic areas were considerably larger.

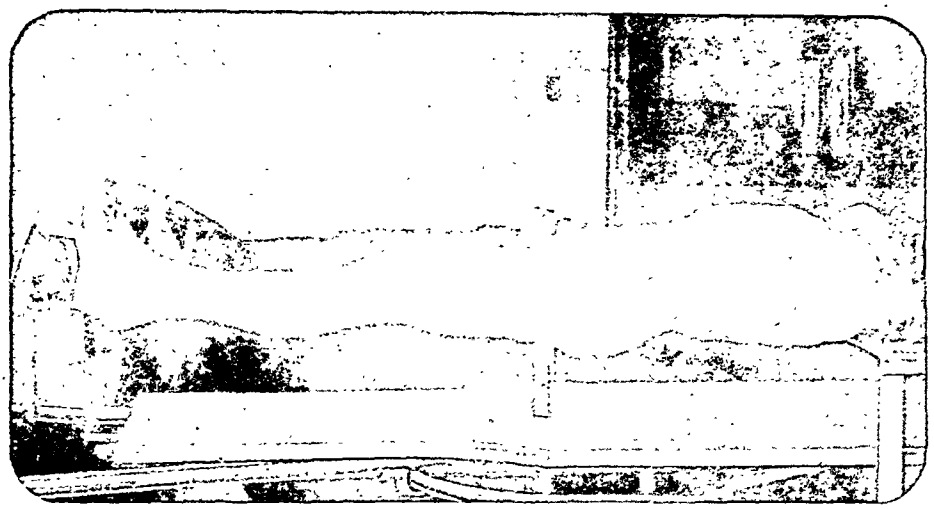
These facts should be taken in conjunction with the observation that the areas of haemorrhagic consolidation were surrounded by deep zones of recent bleeding, and we are inclined to believe that patients who develop pulmonary haemorrhages without external trauma to the thoracic wall after the detonation of high explosive continue to bleed into the lung for a period which may amount to forty-eight hours or so.

It would be dangerous to draw any definite therapeutic conclusions from a single case observed for so short a period. It seems probable, however, that on admission the patient was suffering from acute pulmonary congestion bordering on acute pulmonary oedema, and that venesection might well have been performed earlier. The use of concentrated serum was considered, and might have been employed. It also seemed clear that at 5 a.m. the patient passed into a state of "shock" and that the great improvement following venesection had led to a false sense of security. Although he was asleep his blood pressure should have been taken more often, and a plasma transfusion should have been given when it had fallen.

This patient also illustrates the dangers involved in transport by ambulance. When he left thirty-six hours after the explosion his condition had improved and, in the consultation which decided his transfer, he was considered to be quite fit for the journey. When first seen by us his condition was poor and gave obvious cause for anxiety. In the light of the post-mortem finding of continued bleeding it seems clear that these patients should be rested as strictly as if they had had recent severe haemoptysis.

The interpretation of the signs referable to the cardiovascular system is difficult. The bubbling rales in the lungs with dyspnoea and engorgement of the vessels of the neck suggested severe congestion of the pulmonary vascular bed, and this interpretation was supported by the marked improvement after venesection and by the post-mortem appearance of the lung. On the other hand, if there was any change in the blood pressure it was in the nature of a rise, and it is not easy to reconcile this with any serious impairment of blood flow through the lungs.

Summary



A case is reported in which a man aged 23 lived for fifty-one hours after exposure to the detonation of high explosive.

The clinical picture is described and certain suggestions as to treatment are made.

Reasons are given for regarding the pulmonary haemorrhage as being progressive and associated with pulmonary congestion.

Throughout the areas of haemorrhagic consolidation in the lung there were many foci superficially resembling pneumonic consolidation; these are described.

We are greatly indebted to Dr. J. N. O'Reilly for his co-operation in the investigation of this case.

The uses of wide 'Cellona' – hip spica plaster

THE hip spica plaster made from wide 'Cellona' is applied in three pieces—posterior body piece, anterior body piece and leg piece, each cut from seven layers of 24-ins. wide 'Cellona' material. The application of the plaster is completed and the cast trimmed within 15 minutes. It weighs 7 lbs. when dry.

'Cellona' material in widths of 18, 24, and 36 ins. by 6 yards or 12 yards long has been found by practical experience to offer unique advantages in the construction of large plasters and in preparing slabs for the "closed" treatment of all compound fractures, burns and war injuries.

'Cellona' incorporating a specially strong base cloth is also available in the following sizes :—6 ins. by 4 yds., 8 ins. by 4 yds, 4 ins. by 6 yds., 6 ins. by 6 yds., 8 ins. by 6 yds.

Jackets, fillets, spicas, shells and other large plasters made from 'Cellona' are remarkable for their exceptional strength and resilience.

Milton treatment of wounds

This treatment proceeds by three stages:—

1. MILTON 50% DILUTION

Thorough cleansing and mechanical removal of all infected plasma proteids, necrotic tissue and pus. Milton dissolves this detritus and rapidly sterilises the clean surface. As a hypertonic saline it produces profuse fluid exudation.

"*The process of mechanical cleansing is of most advantage in wounds containing sloughs and is well served by solutions containing chlorine or liberating oxygen, both of which tend to disintegrate and detach necrotic tissue.*"—*Lancet, May* 4, 1940.*

"*The most rapidly acting antiseptics are the halogens and those liberating nascent oxygen.*" —*Lancet, April* 27, 1940.*

"*Profuse fluid exudation can be deliberately produced by applying hypertonic solutions of salt.*"—*Lancet, May* 4, 1940.*

2. MILTON 5% DILUTION

The clean wound is kept sterile by an isotonic antiseptic protective layer, applied by dressing, irrigation or immersion. In this mild aqueous medium a normal granulation proceeds.

"*The proper vehicle for an antiseptic to be applied to a wound is water, and the solution should if possible be rendered isotonic.*"—*Lancet, May* 4, 1940.*

3. MILTON ½% DILUTION

The Milton is then reduced to ½ per cent. at which dilution the hypochlorite has been found to actually stimulate cell-division and tissue-growth, with consequent rapid healing.

After débridement, this course of treatment is normally painless.

This therapy cannot be carried out with full success by the use of Dakin's solution or of Liq. Sod. Chlorin., owing to their causticity, their deficient saline content and to their varying strength of hypochlorite.

* *Prevention and Treatment of Wound Infection.*
Action of Antiseptics on Wounds.

Milton the stable sodium hypochlorite

non-irritant and of standard strength

HAEMORRHAGE INTO THE LUNGS IN CASES OF DEATH DUE TO TRAUMA

BY

JOAN M. ROSS, M.D.
Pathologist in the E.M.S.

When changing circumstances bring a lesion to the notice of a morbid anatomist as a manifestation of a new aetiological factor it is well to review the past experience of the lesion and to detail, so far as possible, the variations that have been observed. Under war conditions fatalities have occurred in which the outstanding post-mortem finding has been haemorrhage into the tissue of the lung. Reviewing the peacetime incidence of haemorrhage into the lung in association with death from trauma, it must be recalled that such a lesion may occur in various conditions.

Peacetime Injuries

Blood may be inhaled after haemorrhage from lesions of the upper air passages or nasopharynx, or even from a fracture of the base of the skull. The blood in these cases will be found in the bronchi, bronchioles, and filling the respiratory bronchioles and alveoli in a lobule, giving the appearance of haemorrhagic areas approximately wedge-shaped but with lobulated margins. These bloody foci are likely to be more numerous in the lower lobes. The lung tissue is undamaged, and in the absence of previous pulmonary disease the microscopical appearance is that of normal respiratory bronchioles and alveoli filled with fresh blood. In cases in which the inhalation is not immediately fatal coagulation of the blood will have taken place.

A lacerated wound of the lung associated with haemorrhage may occur after penetration of the chest wall by a sharp object—the spike of an iron railing, a part of a motor-car, or some weapon: a similar condition in the lung is produced by a broken rib if driven inwards. The appearances here vary according to whether the penetrating object or rib remains in the lung while respiration continues. The pleura being damaged, there will probably be a pneumothorax and probably also a haemothorax. The injury to the pleura and gross disruption of the tissue of the lung are usually apparent on naked-eye examination. The resultant haemorrhage into the lung varies with circumstances. It may spread for some little distance beyond the margins of the wound.

Haemorrhagic lesions (contusions or bruises) of the lung may be found in cases which show no penetrating wound of the chest and even those in which no ribs are broken and no injury to the chest wall is apparent. Such cases are comparatively frequent in road accidents: they may be found after the violent impact of a moving vehicle or when the victim is hurled against a hard obstacle such as a wall. In children it is most often associated with a history of the rapid passage of a wheel over the thorax. The presence of extensive internal injuries without external evidence of violence is much more common in children than in adults. The haemorrhagic lesion in the lung takes the form of a contusion or localized bruise of some part of the organ, the localization being determined by the direction of the force and the situation of the maximum point of impact on the chest wall. Quite often there is a separation of the lung tissue where the organ has been nipped against the vertebral column. Scattered multiple haemorrhages are infrequent. As a rule there is no associated emphysema, but patients surviving for a few minutes may show all grades of interstitial emphysema when the lung is severely contused. Haemothorax is quite common. Microscopically there is rupture of the lung tissue and haemorrhage into the damaged area.

In another group of cases death may be said to be due to asphyxia. It has been recognized since Tardieu's time that asphyxia from any cause produces haemorrhagic lesions in the lungs. The lesions consist of punctiform subpleural haemorrhagic patches. They are dark in colour and vary in size from 1 to 5 mm. in diameter. Sometimes they are larger. These ecchymoses—Tardieu's spots—are sometimes separated, sometimes in groups. The outline is generally distinct and well defined on the surface. They are most common about the root of the lung at the lower margin and on the pleural surfaces between the lobes. They are usually associated with similar lesions on the other serous surfaces—the pericardium and the peritoneal surface of the diaphragm, etc.—and in the thymus in children. On suffocation the lungs will show congestion as well as Tardieu's spots. In asphyxia due to pressure on the trachea (strangulation) there will be frothy blood-stained mucous fluid in the upper air passages and intense congestion of the lungs, and, in addition to Tardieu's spots, larger patches of haemorrhages may be present in the substance of the lung. Where there has been continued compression of the thorax the haemorrhage into the tissue of the lung will be greatest where the ribs have pressed against the pleura.

Another type of case in which localized haemorrhagic lesions have been said to occur is that in which fat embolism is the cause of death. With reference to this it may be stated that it is not the experience of most morbid anatomists who have dealt with any numbers of deaths of a violent nature that fat embolism of the lung produces any localized haemorrhagic lesions which can be distinguished macroscopically. The lungs of patients dying of fat embolism following crushing injury to the bones, joints, or adipose tissue are typically deeply congested throughout, with no localized haemorrhagic patches.

Wartime Injuries

Having reviewed the haemorrhagic lesions of the lung due to trauma as they were seen in peacetime, it remains to compare the lesions produced as the result of the detonation of high explosive. It is possible to place some cases in the groups already summarized.

Flying missiles—bomb-casing and secondary mobilized fragments of masonry, metal, or wood—produce penetrating wounds of the chest and lacerated wounds of the lung differing in no way, except in degree, from those lesions described above. Impact damage from these missiles, or forcible hurling of the victim by the force of the explosion ("blast"), may produce contusions of the lung such as are all too familiar in road accidents. These contusions may presumably be found without visible external injury.

Cases of asphyxia are probably frequent under conditions due to bombing, where casualties may be buried under debris. These cases may be considered in two groups: in the one there has been inhalation of a large amount of dust: in the other the victim has been pinned under a pile of debris. In the former group the post-mortem findings are those of asphyxia only. Cyanosis is present: frothy mucus may be mixed with the solid inhaled material: and the lungs show congestion and some small scattered haemorrhages throughout and Tardieu's spots on the pleural surface. These ecchymoses are found in varying numbers under the parietal pleura and on the

peritoneal surface of the diaphragm. The other group is of considerable interest as it is possible to construct from examination of these cases a picture of the lung changes in compression asphyxia.

In cases of compression asphyxia where the victim has been buried under debris death has presumably been slow, with attempts at respiration. In such conditions rib markings have been observed; a dark purple line of the size and direction of the rib is seen, with emphysematous bullae visible at the margin of the dark rib marking. In addition these cases showed some scattered haemorrhages into the lung, with subpleural Tardieu's spots. There are localized areas of collapse. Microscopically there is disruption of the alveolar walls where the rib marking has been sectioned. There is fresh blood in the alveoli, and clotting may have begun in some areas. Elsewhere there is general congestion of all the capillaries in the alveolar walls and a considerable number of thromboses in smaller arterioles and veins. Oedema is present in many areas.

So far it has been possible to correlate these wartime injuries with peacetime parallels. Another group is without parallel. This includes cases in which death may be found to have occurred without or with only trifling external injury, but in which intrapulmonary haemorrhage has been a post-mortem feature common to them all. These cases have all been found near to the site of explosion of a bomb. In view of this fact the condition may well be called "haemorrhagic pulmonary concussion"; it may or may not be due to blast from the high explosive. It may prove to be of interest in the elucidation of the actual causes of this concussion that where these pulmonary lesions have been found and there have been external markings of small splinters, etc., the superficial lesions have all been on the anterior surface of the body.

Subpleural haemorrhages are not conspicuous and haemorrhagic rib markings are not present in the pleura. The haemorrhagic areas are scattered through, and often deep in, the substance of the lung, most often posteriorly and towards the base. The degree of haemorrhage varies considerably, but both lungs are affected to the same degree.

Comparing the histology of these cases with that found in compression asphyxia, it is seen that oedema is not a feature. Thromboses are not present. The haemorrhage in those patients found dead is fresh, and clotting has not occurred. There is widespread and intense capillary congestion in the lungs. There is haemorrhage into the walls of the small bronchioles, but absence of bleeding into the walls of the bronchi. There is some over-distension of air vesicles and respiratory bronchioles in some cases, but there is no anatomical relation of these to the ribs.

At the present time it is not known how many of the air-raid casualties dying with gross fatal injury, apparent externally, show pulmonary lesions such as these, but it is beyond question that these appearances are a definite morbid entity distinct from conditions hitherto familiar, and are distinguishable on careful analysis from lesions due to compression asphyxia or to pulmonary haemorrhage due to impact of solids against the thoracic wall.

Conclusion

The main points of difference may be summarized as follows:

In compression asphyxia the lesions may be symmetrical on both sides, but not necessarily so. The haemorrhages are usually subpleural and in the lines of the ribs. Emphysema may outline these rib markings. There is generalized congestion of the lungs and some oedema. Tardieu's spots are nearly always found.

In haemorrhage due to impact of a solid the haemorrhage is in relation to the point of maximum impact and may be unilateral. The lung tissue is contused, torn, and filled with blood at or around this point.

In haemorrhagic concussion the lesions are always bilateral and roughly symmetrical. There is general congestion of the lungs. Pleural haemorrhages are present only as an extension from deeper areas.

FAMILIAL PERIODIC PARALYSIS

BY

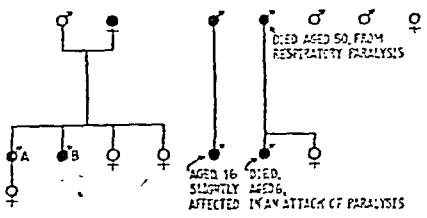
J. MacDONALD HOLMES, M.D., M.R.C.P.

Physician, Staffordshire General Infirmary; Major, R.A.M.C., Medical Specialist

The following brief study of two cases of familial periodic paralysis is recorded because of the rarity of the disease. The patients were brothers recently enlisted in different units, and their disability was first noticed after exercise. The chemical investigations were limited by military conditions and are by no means complete.

Familial periodic paralysis is characterized by sudden attacks of flaccid paralysis in one or more muscle groups, generally in the limbs. The paralysis is usually symmetrical. The trunk muscles are seldom involved, and much more rarely the muscles supplied by the cranial nerves. There is a complete loss or diminution of the tendon reflexes in the affected muscles, and usually the electrical excitability to both faradic and galvanic currents is lost or diminished. The duration of the attacks varies from a few hours to three or four days. They vary greatly in frequency, occurring every few days or at intervals of several months. Sphincter control is rarely affected, and very infrequently death occurs from respiratory paralysis. Biemond and Daniels (1934) have described a muscular atrophy developing in later life in the muscles most affected by the paralysis, but this complication is rare. There is usually little difficulty in diagnosing the cases with a familial incidence, but occasional sporadic cases occur which may be regarded as hysteria.

Until recently the factors causing the disease, apart from the inherited predisposition, have remained obscure. The first real advance in the understanding of the condition was made by Aitken, Allott, Castleden, and Walker (1937). These observers found that during the attacks of paralysis there was an abnormally low serum-potassium level and that the paralysis could be cut short by the administration of potassium chloride by mouth. They also found that paralysis could be induced by giving large amounts of glucose by mouth, either alone or together with insulin injections. These observations were confirmed in two further cases by Allott and McArdle (1938).



The fall in the serum-potassium content had been observed by Biemond and Daniels (1934), but they did not realize its significance. Treatment with potassium salts was mentioned as early as 1902 by Mitchell, Flexner, and Edsell, also by Holtzapple in 1904, and by Herrington in 1937. Holtzapple used potassium bromide, and ascribed the benefit to the bromide rather than to the potassium. Herrington used potassium citrate in 5-gramme doses with success in two cases.

In the first case here recorded the attacks of paralysis could be induced by giving large doses of glucose. During an attack the serum-potassium level was found to be low. Potassium salts by mouth caused a rapid disappearance of the paralysis, with a simultaneous rise in the serum-potassium level. Attempts to induce paralysis in the second case were unsuccessful, and apart from the history there is no definite evidence that this patient suffered from the disease.

Case I

Gunner A, aged 26, was admitted to hospital with flaccid paralysis of the arms and legs following a strenuous day of physical training. When seen the paralysis had almost recovered, but he stated that he had had similar attacks since the age of 15, occurring at varying intervals, usually of a few weeks. All four limbs are paralysed during the attacks and often the muscles of the back as well. Speech is not affected, but occasionally swallowing is difficult. Severe exercise will bring on an attack the following day. He also states that a few glasses of beer will precipitate an attack. The paralysis lasts for three or four days as a rule, and some residual stiffness and aching persists in the affected muscles for about a week afterwards. He has warning of the onset in the form of a "tight feeling" in the arms, legs, and back. He feels very thirsty during an attack, but not hungry. No palpitation or dyspnoea has occurred, nor has there been any loss of sphincter control.

His mother is slightly affected, but with advancing years her attacks have practically disappeared. One brother (Case II) is affected. The accompanying family tree shows that seven members of the family are known to have been affected; these are shown in black.

A complete physical examination revealed no abnormality during a period of freedom from paralysis. There was no muscular wasting, and all the tendon jerks were brisk. The electrical reactions of all the muscles were normal. The administration of glucose in 50-gramme doses with 25 units of insulin three times a day did not induce paralysis, nor did the injection of adrenaline in 5-minim doses half-hourly for twelve hours.

On April 2, 1940, 200 grammes of glucose was given at 10 a.m. An attack of paralysis began about 1 a.m. the following day. Weakness was maximal in the upper arms, back, and legs. The forearms were only slightly weak and toe-wriggling movements could be performed. All the tendon jerks were absent with the exception of those of both triceps and the knees, which could just be elicited. The pulse-rate remained unchanged, the blood pressure was 130/75. There were no sensory changes apart from tenderness and aching of the muscles involved. Twelve grammes of potassium chloride was given by mouth at 10 a.m. on April 3. The paralysis had completely disappeared by noon, but some stiffness and aching remained. The tendon jerks all reappeared as the paralysis was passing off. The potassium chloride produced severe nausea, so it was decided to use potassium citrate on future occasions. A fractional test meal showed a normal secretion of free hydrochloric acid, and a glucose-tolerance curve was normal.

On April 17 another attack of paralysis was induced by giving a further 200 grammes of glucose at 10.30 a.m. As before, the onset of paralysis was about 1 a.m. the following day. The serum-potassium level at 10 a.m. on the 17th was 18.9 mg. per 100 c.cm. On this occasion all the tendon jerks disappeared, and the electrical reactions were present but sluggish in the affected muscles. Serum-potassium and blood-sugar estimations were made during the period of recovery and the following figures were obtained:

	Serum Potassium	Blood Sugar
April 18:		
10.30 a.m.	12 mg. per 100 c.cm.	110 mg. per 100 c.cm.
15 grammes of potassium citrate then given. Rapid recovery followed.		
11 a.m.	18 mg. per 100 c.cm.	
11.30 a.m.	21.8 " " " "	110 mg. per 100 c.cm.
12 noon	23.3 " " " "	
2 p.m.	20.1 " " " "	90 " " " "

The tendon jerks were present at 11 a.m. and had fully returned at 2 p.m.

The urinary excretion of potassium was estimated during the two days covering the period of paralysis and the following figures were obtained:

	Urinary Excretion of Potassium
April 17.	
Between 10 a.m. and midnight	0.19 gm.
April 18:	
Between midnight and 10.30 a.m.	0.172 gm.
" 10.30 a.m. and 2.30 p.m.	0.126 gm.
" 2.30 p.m. and 9.30 p.m.	2.964 gm.
" 9.30 p.m. and 5.30 a.m.	1.5 gm.

Case II

Private B, aged 23, the younger brother of Gunner A, stated that his first attack of paralysis occurred at the age of 17. The attacks are infrequent and by no means as severe as those of his brother. They are brought on by severe exercise, and he has had one attack since he joined the Army—following a long route march. As in Case I, the paralysis usually occurs when he is in bed at night, and when severe it lasts for two or three days. He has no premonitory signs or symptoms.

On April 26 physical examination revealed no abnormality. All attempts to induce an attack of paralysis failed. Glucose alone, glucose with insulin, and adrenaline did not cause the slightest muscular weakness. The following serum-potassium and blood-sugar estimations were made:

	Serum Potassium	Blood Sugar
April 29.		
1.30 p.m.	24 mg. per 100 c.cm.	116 mg. per 100 c.cm.
200 grammes of glucose then given by mouth		
2.45 p.m.	25.7 mg., but some haemolysis had occurred	
3.15 p.m.	21.9 mg. per 100 c.cm.	116 " " " "
4.15 p.m.	21.9 " " " "	116 " " " "
7.15 p.m.	19.35 " " " "	110 " " " "
11.30 p.m.	16.93 " " " "	
April 30:		
8.30 a.m.	21.9 " " " "	
2.15 p.m.	22.5 " " " "	

The investigation of this case was not pursued further.

Commentary

The low level of the serum-potassium content during the period of paralysis in Case I and the rapid recovery following the giving of potassium salts by mouth correspond with the observations of Aitken, Allott, Castleden, and Walker (1937) and Allott and McArdle (1938). The estimations of the urinary excretion of potassium, although incomplete, suggest that there was a retention of potassium in the body during the period of paralysis and its onset.

Ferrebee, Atchley, and Loeb (1938), and Pudenz, McIntosh, and McEachern (1938) showed that potassium is retained in the body during the attacks of paralysis. Gammon, Austin, Blithe, and Reid (1939) have shown that in the late hours of the night potassium excretion

was unusually low and that water diuresis rapidly washed out potassium from their patient, with a fall in the serum potassium and development of paralysis. Pudenz, McIntosh, and McEachern found that if the venous return of one arm was obstructed the injection of potassium chloride into an artery of the limb did not produce a return of function. If, however, the circulation of the limb was completely obstructed injection of potassium chloride into the other arm produced a return of function equally quickly in both limbs. They therefore suggested that a central factor may be at work. It has been shown that intravenous injection of choline esters such as doryl and mecholyl will cut short an attack of paralysis without the administration of potassium, and that after these drugs the serum potassium rises.

An interesting similarity to the action of potassium in familial periodic paralysis occurs in myasthenia gravis. Laurent and Walther (1935) first showed that potassium salts were a valuable adjuvant to prostigmin in the latter condition and might even replace it in some cases. Cumings (1939, 1940) has shown that there is a retention of potassium in the muscle substance during the periods of weakness in myasthenia gravis.

Our knowledge of the mechanisms involved in the causation of attacks of familial periodic paralysis is still very incomplete, but the available evidence suggests that an abnormal metabolic process in the muscle fibres is responsible, and not any central factor in the nervous system. Allott and McArdle (1938) found that the phosphorus metabolism runs parallel with that of potassium and suggest that a quantitative or qualitative disturbance of hexose phosphate metabolism is involved. The similarity to myasthenia gravis suggests that there may be common factors in the two conditions.

The serum potassium was estimated colorimetrically by a cobaltinitrite precipitation method. The same method was applied to the urine after making it alkaline and removing the ammonia by adding formaldehyde.

Dr. John E. Gordon, Professor of Preventive Medicine and Epidemiology at Harvard University, has made a brief statement of his plans for setting up in this country the American Red Cross Harvard Hospital for Infectious Diseases. The plan envisages three distinct activities: (1) the hospital proper for the care of patients; (2) research laboratories for the study of clinical problems and epidemiology; (3) field study in epidemiology and infectious diseases. Dr. Paul V. Beeson, formerly of the Rockefeller Institute Hospital in New York, will be in charge of the hospital; Dr. MacNair Scott, Research Professor of Pediatrics at the University of Pennsylvania, will supervise the laboratory work; Dr. John Mote, Assistant in Epidemiology at Harvard Medical School, will undertake epidemiological investigations; and field studies will be under the direction of Dr. Dean Fleming of the Harvard School of Public Health.

SOME PUBLIC HEALTH CONSIDERATIONS CONSEQUENT UPON A LARGE-SCALE AIR RAID

BY

ARTHUR MASSEY, M.D., D.P.H.

Medical Officer of Health, City of Coventry

The enemy air raid on Coventry on the night of November 14–15, 1940, was of great severity and the casualties were heavy. Damage to property in the city was widespread and included much injury to drainage, sewerage, and water communications. The social disturbance as affecting the lives and habits of the civil population was considerable, and, following the raid, evacuation—official and private—was on a large scale. This was due to the big number of damaged houses temporarily uninhabitable and to the hazard of further raids. In addition to the "complete" evacuees there was a larger number of those who continued to work in the city by day and to sleep elsewhere. The still commendably large residual adult population who "stuck it" in the city have had to take to shelter life to a greater extent than obtains in areas hitherto comparatively free from bombardment. All these things have brought momentous public health considerations in train, notably in the spheres of epidemiology, hospital policy, mental health, and housing. In these connexions the following brief notes may be of interest.

Epidemiological

In view of damage to drainage and water mains the typhoid hazard was obvious, and the preventive measures adopted included (*a*) persistent local propaganda urging the boiling of drinking-water and milk; (*b*) the chlorination of water supplies; (*c*) special injunctions to and supervision of makers and purveyors of foodstuffs in regard to cleanliness; (*d*) all possible steps to secure the early restoration of water-pipes, sewers, and drains; and (*e*) arrangements for large-scale anti-typhoid inoculation.

In regard to (*a*), Press, posters, and Ministry of Information loud-speaker vans were used. The absence of gas supplies in many parts of the city added difficulty to the boiling of water and milk, but the public nevertheless took the matter seriously and resorted to open fires for boiling.

Immunization against Typhoid.—The view of the Ministry of Health in regard to mass immunization against organisms of the typhoid group is that there is no occasion for it unless conditions should arise which, in the opinion of the medical officer of health, render it necessary. The conditions which arose in Coventry following the big raid were exactly such as presumably were meant when the latter proviso was inserted.

Immediately after the raid three immunization clinics were opened at convenient points in the city—namely, at two hospitals and at a large central first-aid post. In addition one of the mobile first-aid units was commissioned temporarily as a mobile immunization clinic. These clinics were conducted by medical and nursing personnel of the public health department. Arrangements were made for the employees of large factories to be inoculated at the factories. The immunizing material was supplied free by the department, and the firms concerned contracted with private medical practitioners for the inoculation work. The campaign was well advertised by Press, posters, and loud-speaker vans. The immunizing material

used was Lister Institute anti-typhoid-paratyphoid A, B, and C vaccine, supplied through the Ministry of Health. In addition a certain amount of Evans Sons Lescher and Webb's anti-typhoid-paratyphoid A and B vaccine was employed. The injections were made subcutaneously in the left upper arm. During the first three weeks following the raid the numbers of persons immunized were: At the clinics, 2,364; in the factories, 13,417; privately, 505. The work is still proceeding apace, although the law of diminishing returns is beginning to assert itself. Notably in regard to workers in factories, there was some little apprehension at first regarding the possibility of loss of working time owing to reactions. The inoculations were done at times which minimized this possibility, and in fact initial misgivings proved to be unwarranted.

Shelter Dangers.—Much has already been written in regard to the unhappy epidemiological potentialities of shelter life. The danger applies fully in a proven target area where, since raids began, shelter life is regular and general. In such an area the risk of an unusual incidence of diphtheria, cerebrospinal fever, influenza, and the like is real. Measures of prevention in the shelters may be classified as environmental, supervisory, and educative. The best general measure is a strong evacuation policy applied to women and children. So far as diphtheria is concerned mass immunization of children is in any case important and necessary. The open phthisis case is a constant problem in public shelters, and the medical or nursing adviser should essay to secure that infectious cases of this kind refrain from using the shelters. Dispersal in small shelters as opposed to concentration in large ones would do much to counter the spread of infections, but, of course, many other important considerations must influence shelter policy.

Baths.—The Coventry raid seriously interfered with supplies of water to the public baths, and the bathrooms of a large number of damaged houses were of course unusable—just at a time when bathing facilities were especially necessary to help to counter possible infections and parasitic conditions. Water-supplies were quickly restored to the undamaged first-aid posts, however, and the shower-baths in the decontamination units there were made available to the public and were much used. Requests were made to the factories possessing similar facilities to throw them open to workers and their families, and a good response was forthcoming. The local policy of providing rain-water tanks in connexion with house property proved its value, for in many homes where the town's water was cut off rain-water was still available for washing purposes.

Hospital Policy

If further evidence were needed in favour of peripheral as opposed to central sites for hospitals connected with large towns air-raid conditions have supplied it. In Coventry the two large general hospitals are situated centrally, and both sustained damage in the big raid. Owing to the extensive damage the number of beds has been so reduced that each hospital constitutes only a casualty clearing station together with a pool of beds for the temporary accommodation of ordinary acute cases pending evacuation as the pool fills up. The scheme of affiliated outer base hospitals, as planned for the region by the Ministry of Health, has proved invaluable, and the evacuation and other arrangements have worked smoothly under test. It was fortunate that the central hospitals in Coventry had been largely evacuated in readiness before the big raid came. The provision of peripheral in place of central casualty clearing stations may well be a future requirement.

At present the committee of the city's large voluntary hospital is concerned about the future of the hospital, which sustained very extensive damage. All are agreed that full restoration on the existing central site is contra-indicated so long as air-raid risks continue. On the other hand, are the large and excellent administrative and clinical resources of the hospital to be employed only in the restricted sphere of an institution with less than a half of its former beds? The solution is likely to be found in two ways—namely, (*a*) by employing certain resources in the general hospital services of the region, and (*b*) by taking over some large block of buildings in an outside area and staffing and equipping it as a branch of the central parent hospital.

Mental Health

During and shortly after the raid many cases of mental distress found their way to the first-aid posts, for rest and sympathy. They can best be described as having been "stunned" by events. In the main their condition soon became normal. On the whole the reaction of the population was one of calm defiance. Doubtless there was a proportion of neurotic subjects, notably among the hasty evacuees. Actually there has been a decrease in the numbers of patients attending the psychological out-patient clinics held twice weekly in the city. This is probably due to (*a*) the decrease in the city population due to evacuation, and (*b*) the likelihood that the clinic patients—actual or potential—were among the first to evacuate. Nevertheless it cannot be said that there is evidence of any notable increase in the incidence of neurosis. Coventry has suffered many previous raids, and it may be that these served to eliminate the more nervous people by evacuation prior to the big raid.

Housing and Feeding

The number of persons homeless owing to the raid was very considerable. These were immediately provided for through the city's emergency rest and food centres, pending more permanent housing arrangements in outside billets and hostels or with relatives and friends. In the latter connexion travel vouchers were issued to a large number to enable them to reach the homes of those willing to accommodate them in other areas.

The damage to houses was in some cases heavy in areas which in normal times would be the subject of slum-clearance measures. In this respect the raid will have some salutary repercussions. It has in fact given to Coventry a unique opportunity for future big-scale replanning on healthy lines, and there is every reason to believe that the opportunity will not be lost. Meanwhile first-aid repair to houses which properly admit of it is in full progress. In connexion with reconstruction works, hostels have been and are being provided for imported workers.

Even at the height of the city's difficulties there was no serious shortage of food, which was brought in under efficient Government arrangements and dispensed through the city's many feeding centres. The situation was assisted by mobile canteens operated by various voluntary organizations. For some days normal milk supplies were held up, and local stocks of dried milk were of particular value. After the raid an important task was that of food salvaging from damaged shops, stores, and hotels. This was collected and sorted by competent inspectors into the three categories—(*a*) fit for human food; (*b*) fit for animal food only; and (*c*) unfit for any use—and was disposed of accordingly. A common cause under category (*c*) was contamination with small particles of broken glass.

At the time of writing (December 16) services have been largely restored, and among the population stabilizing forces are in full evidence. As their houses are repaired the occupants are returning. There has been no outbreak of infectious disease up to date.

INOCULATION WITH T.A.B.C. VACCINE IN SOUTHAMPTON

ANALYSIS OF REACTIONS

BY

H. C. MAURICE WILLIAMS, M.R.C.S., L.R.C.P., D.P.H.

Medical Officer of Health, Southampton

In September, 1940, we initiated in Southampton a campaign to protect the civilian population against the typhoid group of fevers. The response of the public has been encouraging, particularly among the employees of the larger commercial firms, in some of which we have achieved as high an acceptance rate as 80%. It is interesting to note that, although on occasions the local and constitutional reactions caused discomfort, the number of persons who did not return for a second injection was under 1%.

Some local authorities have refrained from carrying out mass inoculations owing to the possible loss of working time among the manual workers in essential war production. An editorial in the *Medical Officer* discredited such a scheme, on the assumption that every person receiving inoculation would be incapacitated for forty-eight hours, and considered that the resultant loss of working days would far outweigh the time lost through the disease. This conclusion was based on the incidence of the disease in peacetime. For this reason I have noted with care the reactions and loss of working time among those who have received the inoculations. Unfortunately it has not been possible to ascertain to the same degree the reactions following the second injection, but from a large number of people who have been interrogated we find that these show little difference.

The Lister Institute T.A.B.C. vaccine was used in the following doses, with fourteen days' interval between the first and second injections: men, 0.5 c.cm. and 1 c.cm.; women, 0.3 c.cm. and 0.6 c.cm. In analysing the reactions males and females have been divided into manual and sedentary workers, and the reactions classified as follows:

1. Slight local reaction—stiffness of the arm with local redness for a period lasting up to forty-eight hours.

2. Severe local reaction—pain and stiffness exceeding forty-eight hours, with redness and swelling extending more than two inches from the site of injection.

3. General reaction. This took several forms, the most common being a feeling of malaise, nausea, giddiness, shivers, and 'flu; it included in a few cases abdominal pain, with diarrhoea, vomiting, and occasional erythematous or urticarial rashes, the last-named being more marked in allergic subjects.

4. Combined reactions: one of the local reactions with a general reaction.

5. No reaction.

Many of the larger firms desired to have their employees split into groups, owing to the possible dislocation of work by incapacitation, but it is shown that among the 10,032 persons investigated the total loss amounted to only thirty days, and no working time was lost by a total of 1,872 male manual workers. Children over 3 years of age receiving the appropriate dose did not show any severe reactions, and in many cases protection against diphtheria was given at the same time without any bad result. It was also noted that those who had severe general reactions usually had mild local reactions.

Analysis of Reactions following the First Injection

Reactions	Females		Males		Total
	Sedentary Workers	Manual Workers	Sedentary Workers	Manual Workers	
Slight local	1,707 (61.45%)	1,766 (67.8%)	1,592 (57.2%)	1,188 (63.4%)	6,253
Severe local ..	50 (1.85%)	70 (2.6%)	38 (1.3%)	50 (2.7%)	208
Combined reaction ..	766 (27.6%)	594 (23%)	992 (35.7%)	508 (27.2%)	2,860
No reaction	253 (9.1%)	172 (6.6%)	160 (5.8%)	126 (6.7%)	711
Number inoculated	2,776	2,602	2,782	1,872	10,032
No. of working days lost	8	7	15	—	30

Before the heavy raids on Southampton between 3,000 and 4,000 persons attended for inoculation each week, but the interruption of the clinic services occasioned by these raids upset the routine, and we are now making use of the mobile first-aid units. These are stationed in different parts of the town every afternoon, and the number of persons attending shows a daily increase. It is of great importance that if large numbers of persons are to be protected in a town a medical officer should be sent to the places of employment, as workers find it difficult to attend public clinics before the early black-out.

Clinical Memoranda

Congenital Obliteration of Bile Ducts with Total Transposition of Viscera

I have failed to trace any references to congenital atresia of the bile ducts occurring in association with complete transposition of the viscera, hence my desire to record the following case. I have found reports of cases in which congenital obliteration of the bile ducts has been described in association with the transposition of some of the viscera, but in none of them does the transposition seem to have been total.

CASE REPORT

A full-term female child—weight 7¼ lb. at birth—was admitted when 6 months old to the Devon and Exeter Hospital bearing the label "icterus neonatorum." The history was that she had been "yellow" since birth. This "yellowness" had steadily increased in intensity, and about six weeks previous to admission the abdomen had gradually become swollen, followed by swelling of the legs and feet; otherwise, according to the parents, the child had been healthy and normal in every way. She was the second of the family, the elder child being perfectly healthy. The father and mother were both healthy and normal. No instance could be elicited of a similar condition in the family history.

On admission the temperature was 99.2°, the pulse 120, and the respirations 48. The infant was well nourished, somewhat anaemic, had marked distension of abdomen, with a moderately intense icterus which involved the whole body, including the conjunctivae. I was unable in my interrogation of the parents to find out whether the jaundice had first appeared in the skin or in the conjunctivae. Both legs were

oedematous and swollen, and there was a haemorrhagic area in the skin on the antero-lateral aspect of the right wrist. The buttocks and labiae were swollen, excoriated, and red. On palpation both liver and spleen seemed to be enlarged. The presence of intraperitoneal fluid was demonstrable.

There was no apex beat visible or palpable on the left side. On auscultation it was discovered that the usual heart sounds heard over the mitral area could be heard much better over a corresponding area on the right side. This led to palpation on the right side, and a faintly palpable beat could be found in the region of fourth and fifth ribs. Dextrocardia was postulated and confirmed at necropsy. There was some dullness in both lung bases, otherwise nothing abnormal was detected in the respiratory system. No evidence of haemorrhage from the umbilical cord was seen nor had the parents noticed any. Stools were, in jaundice parlance, "putty-like." The urine was deeply stained and there was no epistaxis.

A blood examination showed: red cells, 4,240,000 per c.mm.; haemoglobin, 76%; colour index, 0.9; white cells, 62,400 per c.mm.—polymorphonuclears, 61.5%; lymphocytes, 37%; transitional neutrophils, 1%; eosinophils, 0.5%. There was anisocytosis of the red blood cells—some of which were polychromatic—and occasional punctate basophilia. Seven nucleated red blood cells (normoblasts) were seen while counting 200 white blood cells.

The child lived for two days after admission, then died; the temperature having previously risen to 103°.

Post-mortem Examination.—Apart from some congestion, no cerebral abnormality was found. On opening the thorax *complete transposition of the heart and lungs* was observed. Transposition was also found in the abdomen, including the kidneys (as judged by the shape of the suprarenal glands). The heart and lungs showed no other abnormality. There was *half a pint of blood-stained fluid in both pleural sacs*, and about a pint of straw-coloured fluid in the abdomen. The liver was markedly enlarged, hard, tough, and greenish in colour (obstructive biliary cirrhosis). In the position of the gall-bladder there was a thin-walled cyst containing clear greenish-yellow fluid; this, I think, was the gall-bladder—it was about the size of a tangerine. What appeared to be the cystic duct was a fibrous cord lying between the cyst and the liver; it had no connexion with the cyst. The common bile duct could not be traced. The spleen presented a curious condition: there were no fewer than twenty-two splenunculi.

I would like to thank Dr. Seward, honorary assistant physician to this hospital, for permission to report the case, and Dr. Robb, pathologist, for his help and encouragement.

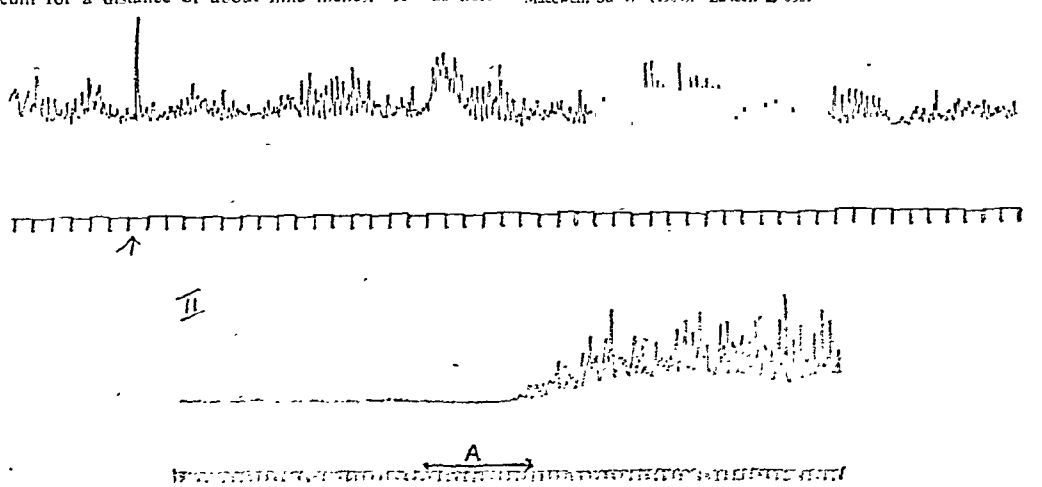
MALACHY J. SMYTH, M.B., B.Ch., B.A.O.,
House-physician, Royal Devon and Exeter Hospital, Exeter.

A Note on the Gastro-Ileac Reflex

An increase in the activity of the colon after the taking of food is a physiological process which is an everyday experience. It is not so well known that a similar reaction occurs in the lower ileum. The term "gastro-ileac reflex" was given to the phenomenon by Sir Arthur Hurst in 1913, although Sir William Macewen described it in 1904.

Observations by Douglas and Mann (1939, 1940) in the dog seemed to indicate that the reaction was not confined to the ileum but occurred also in the jejunum, and, furthermore, depended for its mediation not on the extrinsic nerves of the intestine but on the continuity of the lumen of the intestine. Through the kindness of Prof. Grey Turner I have had the opportunity of studying the reaction in a patient in whom a caecostomy had been established as a preliminary to resection of a colonic carcinoma.

So far as I am aware no record of the reflex has been taken in man. Accordingly a simple air-displacement system was devised, consisting of a small balloon cemented to a gum-elastic catheter, a water manometer, and a recording tambour with a writing lever. The system was connected by pressure tubing. The record was taken on a slow kymograph. The balloon was inserted through the ileo-caecal valve into the ileum for a distance of about nine inches. It was held in position by the patient, the semi-rigidity of the catheter preventing its expulsion. Food was withheld for four hours. The balloon was inflated to a water pressure of about 6 cm., and a control tracing taken. A meal was then given, the tracing being continued.



In the patient, as in the dog, the taking of food was rapidly followed by a well-marked increase in activity (see Figure). At the same time the small-bowel contents were expelled past the balloon into the caecum. It is of interest to note that the time relation of the reaction is similar to that in the dog. The function of the response is probably excretory. The gastro-colic reflex is often followed by defaecation, and it is probable that the gastro-ileac reflex represents defaecation of *the small bowel into the colon.*

Acknowledgment is made to Dr. Allen Daley, Chief Medical Officer to the L.C.C., for permission to publish this observation.

The gastro-ileac reflex in man (upper tracing) and dog (lower tracing). The time intervals in the human tracing are 30 seconds, in the dog 5 seconds. The large excursion in the human tracing immediately after the feeding signal is an artefact caused by the patient's moving while eating.

Reviews

MALIGNANT DISEASE

Malignant Disease and its Treatment by Radium. By Stanford Cade, F.R.C.S. (Pp. 1,280; with 623 illustrations, many in colour. 75s. net.) Bristol: John Wright and Sons, Ltd.; London: Simpkin Marshall, Ltd. 1940.

This book fills a long-felt want and is assured of a hearty welcome. Any one man might well shrink from the attempt to draw the picture of cancer as a whole, for the subject demands at the very least full knowledge of the pathology and natural history of cancer, the wisdom of the experienced general surgeon, and a detailed understanding of the physics and biophysics of radiant energy. Everyone concerned in the treatment of cancer will be under a great debt to Mr. Stanford Cade for succeeding in so immense an undertaking.

The first part of the book contains in a hundred pages a full, accurate, and readable account of radio-activity and radium dosimetry. H. T. Flint, C. W. Wilson, and L. H. Gray have contributed chapters which will enable the clinician to understand the physical principles governing the use of radium, and so, in full co-operation with the physicist, be so much better equipped to treat the patient with cancer.

In the second part of nearly 200 pages the biological effects of radiation are presented in clear and connected detail, and the wealth of references is never allowed to interfere with the continuity and the clinical significance of the facts described. Where all is so good the account of the much-neglected radium burn is outstanding: "It is neither inevitable nor is it of any therapeutic value. It denotes as a rule errors of technique or errors of judgment." The quotation well illustrates the author's vigorous and easy style, which makes the reading of the book as pleasurable as it is profitable.

The third part starts with a succinct account of the limitations of surgery and of the value of radiotherapy, and the author pays his tribute to the pioneer work of the Paris Radium Institute, the Stockholm Radiumhemmet, and the New York Memorial Hospital. If the soundness of their principles had been earlier recognized in England the years spent in using radium for clinical research in general hospitals by methods of trial and error might well have been avoided.

Malignant disease is then considered in every site of the body, a chapter to each: its natural history, clinical types, symptoms (with particular emphasis on the early symptoms as distinct from the textbook descriptions of established disease), histology, local and distant metastases, course, and termination. Next the diagnosis and differential diagnosis are discussed, and then the choice of the method or methods of treatment. The emphasis is always on the value of combined methods of treatment—surgery, surgical diathermy, *x* rays, and the various kinds of radium treatment; the right sequence as shown by experience is indicated, and the technique of radium treatment is given in detail, with illustrative case histories and physical measurements of dosage. The causes of failure are discussed, and the five-year results of the author's cases are set out together with statistics from other cancer centres. Operative details are not as a rule given, but the author lays stress on such points as he has found of importance, such as the removal of the posterior belly of the digastric in a block dissection of the neck. In this connexion, incidentally, he brings the weight of his experience against the so-called prophylactic irradiation of the neck, the value of which is questioned by many radiotherapists.

The value of a book written by one man over that compiled by many specialists is particularly well seen in the chapter on the breast: having, as Mr. Cade says, confused his own mind by the voluminous literature, he comes to clear and fundamental conclusions from the study of his own cases, and the indications for the various methods of treatment are set out with such logic as must command general acceptance. There are naturally many examples in radiotherapy where opinions will differ, and not everyone will support the author's preference for the interstitial treatment of rodent ulcer to surface application; but the case is always fairly presented, and adequate references are given so that the reader may judge for himself. The chapter on cancer of the lung is written by C. Price Thomas, and those on the oesophagus, stomach, and rectum by E. Stanley Lee; these sites are the Cinderellas of radiotherapy, but the reasons for failure and the lines along which advance may be possible are adequately discussed.

With over 600 illustrations, most of them original and many in colour, and a liberal use of charts and tables, the book is an outstanding contribution to radium therapy and a worthy tribute to the Westminster and Mount Vernon Hospital Centres. It summarizes the work of the past twenty years, and will, it is to be hoped, influence the treatment of cancer for another twenty years to come.

MOSQUITO CONTROL

Mosquito Control: Practical Methods for Abatement of Disease Vectors and Pests. By William Brodbeck Herms, Sc.D., and Harold Farnsworth Gray, Gr.P.H. (Pp. 317. $3.50, or 20s. net.) New York: The Commonwealth Fund; London: Oxford University Press. 1940.

In this handsome and attractive volume, illustrated with some excellent photographs and containing useful up-to-date bibliographies to each section, the authors deal very thoroughly with the subject of mosquito control. In reviewing such a work it is perhaps as well to note that there are two distinct aspects or settings to which the term "mosquito control" applies. Mosquito control may form part of operations directed against malaria. There is also, however, the important subject of mosquito control directed against mosquitos themselves as a serious sanitary or even economic problem. This latter form of operation has been greatly developed in America, and in regard more especially to the vast numbers of mosquitos that breed in the salt swamps characteristic of some parts of the coast. Here abatement of the mosquito nuisance is so essential to the carrying on of the normal economic life of the community that it has led to operations on a very large scale, involving great expense and demanding special engineering and administrative experience. Though not entirely restricted to the latter type of operation the volume under review is primarily so concerned. Thus it is possible that the worker on anti-malaria operations, if not warned, might feel some disappointment in that in the many details now developed in the technique relating to anti-malarial measures in tropical countries he scarcely finds what he might feel to be adequate treatment. Nevertheless the book is so thorough in dealing with certain subjects—for example, the principle underlying questions of oils and larvicides, the value of different mosquito ordinances in their actual practical outcome, and many other matters—that even to the worker in the field of malaria control it should be of great value.

On the whole one gathers a most striking impression of the mechanization which has been developed in this setting—the use of the centrifugal pump and mechanical excavators, the dusting of Paris green by aeroplane and by power-operated blower, the power spraying of oil, the motor-cycle oiler and tractor-drawn tracklayer-type oiling

equipment, and other applications of modern developments to facilitate operations. Even if these mechanical applications do not seem to be always very suitable for much of the work which the malariologist has to cope with in the Tropics, such a book as the present one is a stimulus to progress and a reminder to what extent in the modern world mechanization is everywhere coming into the picture.

METHODS OF THERAPY

The Therapeutics of Internal Diseases Volume I: *General Therapeutics, General Therapeutic Technic.* Volume II: *Drugs, Toxicology, Infectious Diseases.* Edited by George Blumer. (Volume I, pp. 872; Volume II, pp. 1,042. Complete in four volumes, cloth, £9 the set.) New York and London: D. Appleton-Century Company.

The first two volumes of this work, edited by Dr. G. Blumer, contain articles by about sixty contributors, the majority of whom are university teachers either of clinical or of laboratory subjects. As regards the general arrangement the text is based upon the description of methods of therapy. About half the first volume is occupied with physical methods, and most of the remainder with endocrine, serum, vaccine, and bacteriophage therapy. The first half of the second volume contains two long articles on pharmacology and toxicology by Prof. Louis Goldman, and the rest of that volume deals with the therapy of infectious diseases. The volumes provide a very useful work of reference regarding modern therapeutic methods. Indeed, the two articles by Prof. Goldman constitute medium-length textbooks.

The compilation of a satisfactory textbook of therapeutics is notoriously a matter of difficulty, since it is necessary to base the general arrangement either on the treatment of patients or on the forms of treatment available for diseases. The latter method has here been adopted, and modern procedures are described very fully, but as a result the work provides no systematic account of the treatment of many common conditions, such, for example, as chronic heart disease and chronic nephritis. This is reflected in the index, which contains one and a half columns under "digitalis," but a mere dozen or so references under "cardiac." Similarly, there are but three references concerning cough, and the only systematic account of its alleviation comprises two pages in the section on chronic pulmonary tuberculosis. These examples indicate the limitations imposed by the arrangement adopted. These limitations certainly must reduce the value of the volumes so far as the general practitioner is concerned. The large number of contributors necessarily involves some lack of balance as regards the amount of space devoted to different subjects. Every subject, however, is treated by a specialist; hence the information provided is of a high standard of accuracy.

The attention given to methods of physical therapy deserves special notice because these are new and of increasing importance; it is not easy to find systematic accounts of their value as full as those provided in these volumes.

THE FOOT AND ANKLE

The Foot and Ankle: Their Injuries, Diseases, Deformities and Disabilities. By Philip Lewin, M.D., F.A.C.S. (Pp. 620; 303 illustrations. 42s. net.) London: Henry Kimpton. 1940.

Already this year two new books devoted exclusively to the foot and published in the United States have been reviewed in these columns; now comes a third, written by Dr. Philip Lewin of Chicago, with the title *The Foot and Ankle.* It is rather larger than its forerunners, and within its 600 pages covers the whole subject very adequately. The production within a year of three books on the same subject would seem to show that the public and the profession are rapidly becoming foot-conscious, no less in the States than in this country. Dr. Dudley Morton's popular book, *Oh Doctor! My Feet!* is an even more certain indication of the interest which the American public now displays in the subject. Although there is no parallel to the latter publication in this country, it may be noted that we set the fashion in books on the foot with those by Ellis and by Walsham and Kent Hughes (now, unfortunately, both out of print) in the last century, and more recently with Lake's *The Foot.*

It is all to the good that interest, both professional and public, in the feet should be renewed, for undoubtedly a large amount of discomfort, inefficiency, and disability arises from foot troubles often in themselves comparatively insignificant.

The book now under review is a notable contribution to the subject in which every aspect is dealt with in considerable detail. The inclusion of the ankle with the foot is logical, and we note that the author very properly also includes such lesions as varicose veins and rickets of the leg. A little more attention might well have been given to the evolution of the foot, for, as previous writers have pointed out, therein lies the primary cause of many foot troubles. However, in a book which is essentially practical and already fairly bulky, it is arguable that such theoretical considerations must give way to matters of direct clinical application. Space will not allow a critical notice of each chapter, but we may take that on flat-foot as a sample. The impression gained here is that the author is somewhat vague as to the exact nature of this condition, and in consequence we find a long list of possible causes. The question "Is the failure primarily muscular or ligamentous?" remains unanswered, and so the indications for treatment are correspondingly indefinite. Such an agnostic attitude is probably justified by our lack of knowledge and agreement upon the many anatomical and physiological features involved, but we feel that the pros and cons of the subject should at least be submitted for the reader's judgment. It will appear rather unusual to the English reader to find so many pages devoted to the treatment of flat-foot by open operation, a procedure very rarely adopted here.

In general this book is an admirable exposition of the subject, well illustrated and well produced. We would end by quoting a wise sentence from the paragraph on "The Mental Attitude of the Patient": "The present success and popularity of quackery and charlatanism should impress upon physicians the importance of treating the mind and the emotions of the patient as well as his physical troubles.

Notes on Books

The treatment of squint in an effective manner might very well be taken as a measure of the grade of the civilization of a people. That was a thought which was impressed upon the mind of the writer when visiting a mid-European country a few years ago. There he saw many children with squints for which it was evident no treatment had been attempted. In this country, happily for the children, parents have learned that a girl with a squint has her prettiness spoiled and that a boy with a cross-eye will be rejected for many a good job. *The treatment of squint may be grouped into three sections:* (1) examination to determine the primary cause and the correction of any error of focus with glasses; (2) special exercises to revive the function of binocular vision; (3) operation in some cases. Section 3 demands much care, skill, and time to carry through the training. Orthoptics is no new line of treatment,

It was first attempted by Erasmus Darwin in 1778; it is likely that the modern development of the art would have intrigued him greatly. To the staff of the Royal Westminster Ophthalmic Hospital we are indebted for the example they have set in the organization of this work. *Practical Orthoptics in the Treatment of Squint*, by Mr. KEITH LYLE and Miss SYLVIA JACKSON, now in its second edition (H. K. Lewis and Co., Ltd., 15s. net), gives a full and valuable account of this treatment and the measure of success that has been obtained by it. This book will be of value to every ophthalmic surgeon, and is a necessary manual for every orthoptist working under the direction of the ophthalmologist.

They Wanted Adventure (Jonathan Cape, 7s. 6d. net) is an essay in fiction by KENNETH MACFARLANE, a pseudonym hiding the identity of the medical author of a most original autobiography. It is a story about two children, a brother and sister, who during a holiday on the west coast of Scotland found themselves taking a leading part in a series of surprisingly exciting events, ranging from the shipwreck of a fishing boat to the discovery of foreign spies in an uninhabited island. For those who are fond of sailing, children, or Scotland this should prove an acceptable book.

Miss EVELYN PEARCE'S *General Textbook of Nursing* (Faber and Faber, 15s. net), promptly recognized on its first appearance in 1937 as one of the best and most comprehensive guides for students and qualified nurses, continues to appear in new guise despite the present conditions. For the fourth edition, now issued, special sections on the treatment of gas casualties and emergency blood transfusion give it topical value, and there are sixty new illustrations, including one of the B.L.B. oxygen apparatus.

Preparations and Appliances

AN IMPROVED STRETCHER CLIP

Dr. J. T. CHALMERS KEDDIE writes:

Much difficulty has been experienced in satisfactorily securing stretchers in ambulances, particularly when carrying out exercises in darkness. The webbing equipment attached to the stretcher-carrying fitments as supplied in accordance with the Ministry of Health Circular 1794 has been found to require a great amount of time to thread through the patent buckles, especially under black-out conditions. A person wearing anti-gas gloves finds the task impossible. Owing to these difficulties personnel are apt to neglect securing the stretchers, and as the Ministry requires these to be greased with vaseline there has been a great tendency for a stretcher to slide on its carriage when the ambulance is in motion, with the result that patient and stretcher are apt to be ejected into the road.

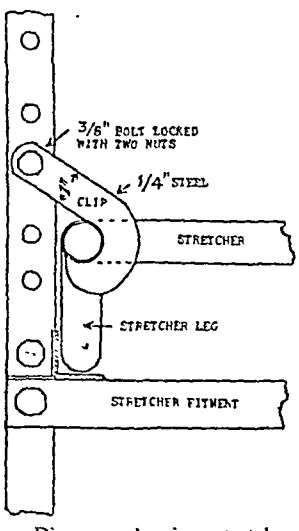

Diagram showing stretcher clip. This fits tight to the stretcher and lifts it 1/8 in. off the carriage; any weight applied on the stretcher binds it firmly to the fitment.

With the above points in mind something simple and cheap had to be designed, and the appended sketch shows a catch which serves the purpose in every way, and also provides for easy and efficient decontamination. If the catch is painted white it is easily seen in the darkness. These clips have been supplied to auxiliary ambulances in use and on "on call" and have proved most efficient.

A NEW HERNIA INSTRUMENT

Dr. HERBERT A. HAXTON (Lecturer in Anatomy, St. Andrews University) writes:

In these present days, when the operation of radical cure of indirect inguinal hernia is being performed on so many of the young men of this country, there is a place for any addition which will make the operation easier to perform and sounder in its end-result. It is with these objects in view that the instrument described below has been evolved. It consists of a body, with a head at one end and a point at the other (Fig. 1). The head is in the form of a broad retractor,

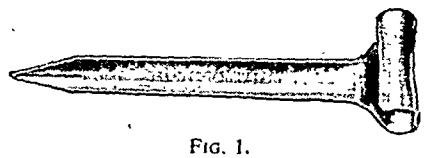

FIG. 1.

one and a half inches across and slightly curved from side to side; the blade of the retractor is curved through three-quarters of a circle. The body is four inches long and half an inch across, and it has a side-to-side curve. It tapers to a rounded point at the end remote from the head, and on this tapered part is a director groove.

This instrument has a threefold use—as a director, as a retractor, and as a depressor. The director is employed in the division of the constricting band of a strangulated hernia, the tapering part of the body protecting the viscus from damage during this manœuvre. The use of the instrument as a retractor is seen in Fig. 2, its purpose being to retract and

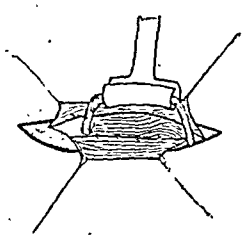

FIG. 2.

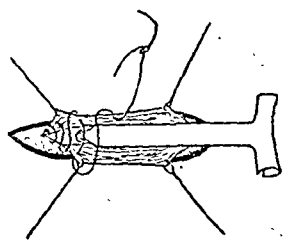

FIG. 3.

protect the spermatic cord during the procedure of suturing the internal oblique muscle and conjoint tendon to the inguinal ligament behind the cord, the essential step of Bassini's herniorrhaphy, which is the operation usually performed for the indirect hernia of the young adult. Since the blade is equal in transverse measurement to the length of the inguinal canal a full retraction of the spermatic cord is possible, so that the suturing can proceed unhampered by its presence. Other devices have been used for this step, such as a strip of gauze or a retracting ring; but these do not give the same complete retraction of the cord, combined with its protection during the introduction of the sutures.

The next step in the operation—the suture of the external oblique aponeurosis superficial to the spermatic cord—is aided by the use of the body of the instrument as a depressor and protector for the cord, as shown in Fig. 3. The procedure is to insert the pointed end in the opening in the internal oblique through which the cord passes, so that the body lies on the superficial aspect of the cord with its concave surface in contact with the latter. (The depth to which the point can be passed into the opening can be used to determine if it is too large, or so small that the veins of the cord will be constricted.) During suture of the external oblique the instrument is maintained in this position, protecting the cord from inclusion in the suture and preventing the soft fat which it contains from insinuating itself between the apposed edges of the aponeurosis, an event which results in weakening of the scar. The instrument is withdrawn on completion of the suture line, and again it acts as a guide for size, this time of the superficial inguinal ring.

The instrument has been made for me by Messrs. Allen and Hanburys, Ltd., to whom acknowledgment is due for their co-operation and for the illustration of the instrument.

BLAST INJURIES

While we are lamenting the loss of our historic monuments it is well to take courage from the toughness of fibre of the human frame. Imagination, fed to some extent by tales spreading from theatres of recent wars, such as Spain, had endowed modern methods of war with far greater destructive power than our experience has shown them to have. Propaganda had played its subtle part in leading everyone, the medical profession included, into believing that modern high explosives had peculiar malignity. It is therefore well that the profession should have opportunity to take stock, sift evidence, and establish the truth as it sees it to-day. A discussion at the Royal Society of Medicine, reported in this week's issue, throws light on some of these beliefs, nursed early in the folds of ignorance, and disposes of much of the supposed malevolence of high explosives. Further clarification comes from the articles in our present issue by Professors Hadfield and Christie (p. 77) and Dr. Joan Ross (p. 79).

During the war of 1914–18 it was no uncommon occurrence to be exposed to and yet live through explosions at close quarters of shells of large calibre. Yet no clear clinical syndrome among soldiers subjected to such an experience emerged, and this might be thought to indicate an absence of injuries as a result of explosive forces alone. The prevailing thought was that the nervous system was particularly sensitive to this form of trauma—a thought which received the support of Mott. However, animal experimentation has established that pulmonary lesions predominate. Recently Sir Joseph Barcroft[1] undertook an investigation into the physiological effects of "blast." These experiments were so arranged that animals (goats) situated in the open and in Anderson shelters were exposed to the intense pressure changes, both of a positive and of a negative character, which are the essential elements of an explosion, following the detonation of a 500-lb. bomb. Measures were adopted to ensure the avoidance of injury by splinters. Four points were established from these experiments: first, that only animals placed in the open and at fifteen feet from the bomb suffered ill effects; secondly, that the Anderson shelters gave immunity at fifteen feet and outwards to "blast" injuries; thirdly, that the animals situated further than fifteen feet suffered no demonstrable lesion of their organs; and, fourthly, that the lesions found in the animals closest to the explosion were essentially in the lungs. Histologically[2] these lesions consisted of bruising of the surface of the lung in the line of the ribs and vertebral borders, and extended for one-quarter to half an inch into the tissue of the lung. Further small haemorrhages were found deep, mainly around the smaller bronchi. From a study of animals kept over a period of some weeks the exposure to "blast" appeared to have had no permanent ill effect. Professor Zuckerman,[3] in a more elaborate investigation designed to determine the mechanism by which the lung lesions were produced, confirmed the maximum insult to the lung tissue in a wide variety of animal species. He further obtained evidence that the lung lesions were the result of the impingement of the positive wave of pressure on the chest wall without bruising the chest wall itself. That lesions could occur elsewhere he was also able to establish, but that if these occurred the damage to the lungs was of such a massive character that the animals were dead. Of comfort to man, it was observed that such lesions were only to be found when the animal was in very close approximation to the explosive—a matter of a few feet—and this was explicable by the physical characters of the wave of pressure, which very rapidly decreased in intensity and consequently in lethal quality as it spread out radially. Two of his observations were of considerable importance in the diagnostic field —the presence of bloody sputum and the characteristic *x*-ray appearance of the chest. In view of such experimental data Professor Zuckerman, at the discussion at the Royal Society of Medicine, wisely stressed the necessity for using the greatest caution in labelling any given condition occurring in man exposed to air raids as resulting from "blast."

Four possible types of injury following a bomb explosion were propounded by Professor Zuckerman: (1) the lesions following the direct effect of "blast" and from the bomb-case splinters; (2) trauma resulting from the subject's being thrown to the ground or against a solid structure by the "blast" wave; (3) injury by secondary missiles, such as wooden beams, masonry, and such-like; (4) injury from exposure to fire or to escaping gas. Were the medical profession to keep such possible causative factors in mind and label accordingly much unwise discussion would be prevented and possibly much needless suffering, both physical and psychological, stopped. Difficulties, however, confront the medical man, for the main factor in determining the causative agent is the obtaining of a very clear history of the incident—an ideal which is not always possible to attain owing to the condition of the injured. Some evidence may be obtained from an estimation of the damage caused by the bomb; but on this aspect the profession awaits help from the appropriate authorities, who could issue, without disclosing information to the enemy, some data regarding the extent of damage from bombs of different calibre and an estimation of the zone of probable lethal "blast" injuries. This would act as a corrective to the natural tendency of all to magnify the size of the bomb and the nearness of themselves to it. With this knowledge the profession would be better armed to deal in a speedy and reliable way with air-raid injuries. There are now, however, available in the literature records of cases suffering from the effects of exposure to high explosives. Dean[4] and his colleagues observed in quite a number of cases symptoms and signs of

[4] Ibid., 224.

pulmonary involvement. Bronchitic changes with fullness of the lower chest and intrapulmonary shadows shown by *x*-ray examination were common. Roberts[5] stressed the danger of giving general anaesthesia in such cases. Hadfield, at the meeting, reported on the pathological lesions found in a series of cases; these were characterized by a macroscopical and microscopical appearance closely akin to that found in the various stages of pneumonia, but more irregular in distribution. Stress was laid by him on the amount of haemorrhage in the alveoli and the marked distension and engorgement of the capillaries. He emphasized that the appearances suggested continuation of the haemorrhage over a period of some days—a point which may explain the relapses which have been noted to occur.

It is too soon to determine in full the required treatment. Adequate rest is essential; and in view of the condition of the lungs found at necropsy, and the embarrassed breathing clinically, oxygen therapy would appear to be worthy of more extensive use. Above all, the knowledge that such damage to the lungs may occur should stimulate all to be watchful for this type of damage among air-raid casualties. The Emergency Medical Service has taken the lead and has circularized its officers. The future should bring greater and more accurate knowledge, but for the public and medical profession there is comfort in the thought that such cases are necessarily uncommon and that shelters, including the Anderson, give a high degree of protection against "blast."

WARTIME MEDICINE IN THE U.S.A.

As everyone knows who follows the news which reaches us daily from America, the Federal Government of the United States is pressing on with preparations for the dual purpose of securing its own national defence and helping us and our allies to a successful conclusion of the war. In this connexion the importance of the medical and allied services is fully recognized. It may be recalled that well before the onset of war the British Medical Association had set up a Central Emergency Committee which surveyed and classified all medical practitioners in the country and recorded their offers of service, and that this committee, enlarged and known now as the Central Medical War Committee, acting through local committees, has become the Government's agent for allocating medical personnel, whether voluntarily or under compulsion, for meeting military or civilian demands. Its functions do not extend to determining whether such demands are justifiable, but it foresaw that some co-ordinating body would be needed to scrutinize the establishments of the various medical services, and made a special point of this in its early negotiations with the Government. Subsequent experience has shown the wisdom of the committee's representations. In the United States the need for such a body has been appreciated. The Selective Training and Service Act, 1940, provides for the registration of more than sixteen million men, the immediate medical examination of two to four millions, and the military training forthwith of several hundred thousand. The view in America is that each stage in this process is of medical and public health importance. A Committee on Medical Preparedness of the American Medical Association has followed our plan of carrying out a survey by questionary of the medical profession, and similar censuses are being conducted in their own field by the American Dental Association, the Nursing Council for National Defence, and the American Hospital Association. It is realized that information ought also to be compiled as to laboratory services and personnel such as that now in the possession of a committee of the Medical Research Council in this country. In some special directions a shortage of trained personnel is anticipated—for example, in caring for the health of workers in the rapidly expanding war industries. The American Medical Association has accordingly urged the Council of National Defence to provide the U.S. Public Health Service with funds for the training of physicians, chemists, engineers, and other professional workers in industrial hygiene.

In the United States, where State governments are interposed between the Federal Government and local authorities, the system has been established by the U.S. Public Health Service of holding periodical conferences in Washington of State and Territorial health officers to discuss matters of common interest. A special conference of this kind was held on September 16 and 17, to which members of the National Advisory Health Council, officials of the Army, Navy, and other branches of the Government, and representatives of professional organizations and voluntary agencies were invited.[1] Its object was to plan and co-ordinate the medical and public health measures necessary for national defence. Surgeon-General Parran emphasized the need for preserving a balance between facilities to care for the civil and industrial population on the one hand and the demands of the military services on the other. This involved special consideration of key personnel in essential health and medical services and schemes of training to ensure an uninterrupted output of professional men and women to meet both civil and military demands. But his outline of the problem and the course of the subsequent deliberations revealed that public health departments in America are thinking of problems arising from the emergency which go far beyond the mere provision and allocation of personnel. Medical examination of recruits will discover many with diseases and defects requiring treatment and the restoration of working capacity which has come to be called rehabilitation. Apart from tuberculosis, which normally falls within the province of governmental care, it appeared to be the general opinion of the conference that the State should make itself responsible for seeing that all those found with defects should receive attention. As a corollary to the recent and vigorous drive against syphilis in America, opinion was unanimous on the desirability of arranging for a voluntary blood test of every man registering, although it was realized that the practical difficulties were enormous. In the course of examination the ascertainment of tuberculosis should be specially stressed and provision made in advance for the immediate treatment of the numerous early cases which would be discovered. The health of communities where training cantonments were set up would require more than usual attention, and the

movement of industrial workers into new areas where munition works are to be established would create problems of health and housing of which we have had experience. The American Navy, for instance, is already faced with the housing of many new hands employed in the Navy yards. It was contemplated that all measures to deal with these problems would be a proper charge against Government funds.

Two days after this conference had met President Roosevelt approved an order creating a Health and Medical Committee. Its function is to advise the Council of National Defence on health and medical problems and to co-ordinate health and medical activities affecting national defence.[2] The new committee is to be executive as well as advisory, being vested with power to use the facilities of the medical departments of the Army, Navy, and Public Health Service, including their laboratories and equipment, and to spend moneys allocated to it on studies, investigations, and reports by such individuals or institutions as it may employ. The wide terms of its reference would appear to cover the knotty problem of priority in demands for medical personnel, although in this respect it may be subject to the overriding authority of the Council of National Defence. The committee consists of Dr. Irvin Abell, a former president of the A.M.A., as chairman, the surgeon-generals of the Army, Navy, and Public Health Service, and the chairman of the Division of Medical Sciences of the National Research Council. Its constitution, it will be observed, is entirely medical. For this reason, and because of its small size, it should be able to exercise that control over medical matters in wartime which many would be glad to see effectively established in this country.

MEDICINE IN A CHANGING WORLD

In his stimulating article on "Trends in Human Nutrition" in our current issue, Sir John Orr, in a passage under the heading of "Medicine and the New World Order," makes a statement of the widest implication to the medical man of to-day and to-morrow. "The medical profession," he writes, "contains within it experts on every subject that affects human welfare. It is the only organized group of men competent to make a statement on human needs." This is certainly a startling claim to make on behalf of any group of men within a modern State, and if it has within it the seeds of exaggeration the sower may be excused, for he brings forcibly to the front ideas that have been simmering in the minds of an increasing number of men who see the art and science of medicine, not merely as the prescribing of pills and the ameliorative use of the knife, but as a contribution to human welfare. This is not to decry the art and the craft that are the foundation of the daily work of the doctor. Knowledge and more exact knowledge is what we need. The new techniques must be increasingly used, and with a thorough understanding of their possibilities of bringing more precise information to bear on the problems of health and disease. It is perhaps a paradox that at the very moment when medicine is acquiring a technical equipment that brings it within the narrowing confines of an exact science, with the inevitable tendency to specialization, it is reaching out to a wider conception of the part it has to play in human society. This paradox is also apparent in the attitude of other workers in pure and applied science. In fact, what we are witnessing is a heightened consciousness of social responsibility in a world in which the forces of disruption are momentarily paramount.

Sir John Orr's suggestion that there are in the ranks of medicine "experts on every subject that affects human welfare" must be examined more closely. Medicine cannot concern itself with the economic man, the political man, the religious man, the legal man. Indeed, it is not competent so to do. There is even the great danger that the doctor, acting as a doctor, may be tempted to prescribe political and economic remedies for what he considers to be medical and sociological ills, and somewhat ostentatiously to ally himself with one or other political movement. Once he is immersed in the heat of political emotions his judgment as a medical man tends to become warped when he looks at medical problems through political glasses. This is perhaps well illustrated by reference to the subject of Sir John Orr's lecture. There is no doubt that the distribution of wealth in this country has made it difficult, and in some cases impossible, for a large section of the population to buy enough of the right kind of food or to live in conditions that make for the maximum possible health. The medical man has investigated in some detail the effects on such a population of malnutrition. He has been rightly concerned with the wider effects on the country as a whole. But for the medical profession, or any section of it, to bring to bear the whole weight of its authority on such a fundamental matter as diet and nutrition it must speak in terms that are strictly medical and physiological, uncontaminated with political partisanship or economic theorizing. The cobbler must stick to his last. As a private citizen the doctor may cast his vote as freely as any other man in a democracy, but we do not believe that medical men, as such, can make any worthy contribution to either medicine or politics by segregating themselves into political groups.

We would modify Sir John Orr's second proposition and restate it in some such terms as follow: "The medical profession has within its numbers those who, more than any other group of men and women, are competent to make a statement on the physiological and psychological needs of human society." We would add, too, that such a statement would be incomplete. Nevertheless it should be made, and in the period of reconstruction to which we look forward some kind of statement will be expected by a country which, in the present terrible struggle, sees justification for it in the promise of a new world—what Mr. Churchill has called "the march of the common people towards their just and true inheritance and towards the broader and fuller life." This must be based on good food, good housing, free opportunity for physical and mental development, and comprehensive medical services for the whole community. The standards for these desiderata can be laid down in a medical charter, and this could be one of medicine's greatest contributions to the new epoch of which the present war is but a sign and a portent.

NEOARSPHENAMINE AND THE SULPHONAMIDES

In the early days of the 1914–18 war, when the science of chemotherapy was still almost synonymous with the study of the arsphenamines, certain striking results were obtained with these arsenicals in the treatment of bacterial infections. Schiemann[1] and others in Germany first showed that both arsphenamine and neoarsphenamine were bactericidal *in vitro* for the organisms of anthrax, glanders, and swine erysipelas. Later, Douglas and Colebrook[2] found that the serum of a patient to whom either arsphenamine or neoarsphenamine had been administered possessed a bactericidal action on staphylococci, while Joanny[3] among others put forward great claims for these compounds in the treatment of puerperal sepsis. Colebrook,[4] however, was less enthusiastic, although sulpharsphenamine appeared to have certain possibilities; with the advent of the sulphonamides these studies seemed, for the moment at least, forgotten. Recently, however, Osgood, Joski, and Brownlee[5] have returned to an investigation of neoarsphenamine in relation to sulphonamide compounds. By growing the cells of the human bone marrow in tissue culture it has been possible to develop a method for the accurate quantitative comparison of therapeutic agents against bacterial infections. When the bone-marrow cultures were infected with *Staph. aureus* it was found that neoarsphenamine in concentrations of 1 in 150,000 to 1 in 200,000 was more effective than either sulphanilamide, sulphapyridine, sulphathiazole, or sulphamethylthiazole. In concentrations of 1 in 10,000 sulphamethylthiazole and sulphathiazole were of considerable value but rarely led to complete sterility; sulphapyridine was only slightly effective and sulphanilamide was practically useless. Concentrations of neoarsphenamine above 1 in 150,000 were toxic to the marrow cells, and concentrations above 1 in 70,000 killed all the cells. These studies certainly suggest that administration of neoarsphenamine in intermittent courses of repeated small doses together with sulphathiazole in doses sufficient to give a blood concentration of 1 in 10,000 is worthy of controlled clinical investigation in serious cases of infection due to *Staph. aureus*. Since sulphamethylthiazole is liable to produce polyneuritis in man, sulphathiazole is the most satisfactory sulphonamide derivative for use in these tests.

SARCOIDOSIS OF BOECK

The history of the disease which still goes by this unsatisfactory name is one of unification by histological study of manifestations which clinically had appeared unrelated. To Schaumann belongs the credit of pointing out that the skin condition originally described by Boeck is only one localization of a process which may also involve many other organs, notably the lymph glands, spleen, and lungs, and there is much to be said for calling the disease by his own name, or for adopting the term "benign lymphogranulomatosis" which he suggested. Other manifestations of the same disease are the uveo-parotid syndrome of Heerfordt and bony changes in the hands and feet to which Jungling gave the name "osteitis multiplex cystica." In all these situations the histological changes produced closely simulate those of a tuberculous lesion in the proliferative stage, but caseation never follows and the ultimate fate of the lesion is usually complete resolution. The varied features of this disease were fully described in this *Journal*[6] two years ago by Bodley Scott, and it has again been fully reviewed by Leitner.[7] Now that its clinical recognition in whatever form has been made feasible, interest is centred on the problem of its aetiology. The structure of the lesion being indistinguishable from that of an early tuberculous focus, the main question is naturally whether the disease is a form of tuberculosis. Tubercle bacilli are not demonstrable in the lesions either directly or even by animal inoculation; the exceptions to this statement undoubtedly represent the coincidence of two conditions, and are no more significant than the occasional occurrence of tubercle bacilli in lymph nodes attacked by lymphadenoma. The majority of patients show no tuberculin sensitivity; indeed, they are said to be more often Mantoux-negative than unaffected persons of the same age. This anomalous finding led Jadassohn to postulate a condition of "positive anergy" in this disease, a term implying that in spite of or in consequence of actual tuberculous infection tuberculin sensitiveness has been abolished or has failed to develop. It occurred to Lemming[8] that this hypothesis could be tested by inoculating cases of the disease with B.C.G., the effect of which is to produce tuberculin sensitiveness in a previously Mantoux-negative or "negatively anergic" normal individual. He accordingly gave 0.05 mg. living B.C.G. to a typical case of uveo-parotitis, and when this was without effect of any kind followed this with a dose three times larger. A local reaction followed with swelling of the regional lymph nodes, but a Mantoux test with 5 mg. of tuberculin was still negative. Not only this, but when one of the affected nodes was excised the changes in it produced by B.C.G. corresponded in certain details rather to those of benign lymphogranulomatosis than to those which usually follow B.C.G. vaccination; the tissues had in fact reacted to vaccination just as they react in the disease itself. Repeated doses of B.C.G. in another case in which mediastinal and other lymph nodes were mainly involved failed to alter the patient's negative Mantoux reaction. While other authors can only report negative findings and speculate on the question of aetiology, these are positive facts which deserve the closest attention. But if this process is indeed tuberculous, it still remains to be explained why a lesion in which no bacilli are demonstrable, in a patient who *ex hypothesi* possesses a considerable degree of immunity, should not only persist for years but continue to develop in fresh situations.

EFFECTS OF PRESSURE ON TISSUES

A man of 185 lb. weight exerts a pressure on the soles of his feet in excess of that needed to support a column of mercury 500 mm. high. Healthy tissues are thus designed to withstand considerable pressures, the degree varying with the different body structures. Abnormal pressures, either internal or external, may lead to important tissue changes—for example, the atrophic changes which take place round a rapidly growing tumour, and the tissue destruction associated with bed-sores. Pressure is also an almost invariable accompaniment of many forms of surgical treatment; every suture and every ligature subjects living tissues to abnormal pressures, and gross pathological changes result from pressure in the case of plaster sores and Volkmann's ischaemic contracture. It has also been shown that free skin transplants are better able to withstand the effects of pressure than are pedicle grafts. John Hunter was one of the first to recognize the pathological effects caused by pressure, and came to the conclusion that internal pressure produced

atrophy and that external pressure produced hypertrophy. It was Paget who pointed out that this was one of the rare instances where Hunter was wrong, and showed that constant pressure leads to atrophic changes and inconstant pressure to hypertrophic changes. He also pointed out that it just happens that intermittent pressures are usually from without, while constant pressures are usually from within. Recently Brooks and Duncan[1] have carried out a series of experiments on the rat's tail to determine the influence of known amounts of pressure applied for measured periods on the various specific tissues. It was found that a pressure of 130 mm. of mercury for eighteen hours (approximately equal to the blood pressure in the rat's tail) was necessary before necrosis developed. One series of animals were then subjected to pressures adequate to produce massive necrosis; the arteries were subsequently injected and found to be patent. Very high pressures caused pathological changes in much shorter times. The tissue changes observed by these workers in a number of experiments included epithelial hyperplasia, scaling, muscle degeneration, replacement fibrosis, and varying degrees of necrosis. There was very little difference in the time required to produce sclerosing myositis and that required to produce massive necrosis. These experiments have a bearing on the question of pathological changes caused by abnormal pressure associated with bedsores, constricting bandages, plasters, tourniquets, and sutures, and may throw light on many of the problems relating to the effects of pressure on tissues. Meanwhile, they are being continued in animals suffering from dietary insufficiency, hyperglycaemia, and alterations in blood pressure.

TREATMENT OF VAGINAL THRUSH

The frequency of thrush as a cause of leucorrhoea is not apparently generally recognized. Liston and Cruickshank[2] found that it accounted for nearly 25% of cases in a series of 200 pregnant women. It appears necessary, therefore, to look for this fungus (*Oïdium albicans*) in all cases of leucorrhoea, and to seek for the hyphal filaments in films made from the white patches which are characteristic of the disease or from vaginal washings. The infection is much commoner in pregnant than in non-pregnant women, and frequently clears up during the puerperium; non-pregnant women often get relief during menstruation. The presence of glucose is favourable to the growth of the parasite, and diabetes mellitus is a predisposing cause, which should always be excluded in non-pregnant cases. While the infection is usually confined to the vagina and surrounding skin, it may affect the cervix and even the uterus and tubes. This should be borne in mind in those cases which either prove resistant to treatment or show a tendency to relapse. Should the infection have passed beyond the cervical canal the patient should be referred to a gynaecologist. In all cases of vaginal thrush it is first necessary to look for and to deal with any contributory factors such as cervical erosion, cervicitis, and tears of the cervix uteri, and then to remember that the infection may affect the surrounding skin, not only of the vulva but also of the pubic region, groins, and upper part of the thighs, causing intense irritation. Various remedies have been recommended. Matters[3] swabs the vaginal walls with hydrogen peroxide or dilute liquor potassae, and after drying them insufflates the vagina with powdered silver picrate in kaolin; alternatively, Bonney's blue may be employed as a paint. Mary Michael-Shaw douches with sodium bicarbonate—one drachm to the pint—and follows this with a tablet of stovarsol nightly for two weeks and then less frequently for four to six weeks or even longer. Negatol as used for trichomonas infestation—a douche of 2½% followed by painting with 100%—and "monsol" 1/200 have given good results. Strong negatol causes the mucous membrane of the vagina to become covered with a thick white film, which after a time is shed gradually or may separate as a complete cast, leaving a healthy epithelial surface underneath. Probably the most efficient remedy and the one that gives the greatest relief to the patient is gentian violet. This is used as an aqueous solution in a strength of 1% to 2% and should be painted on the affected parts twice weekly, special care being taken to include all vaginal folds and especially the posterior fornix. The treatment of vaginal thrush should not be stopped when the signs and symptoms subside, because of the tendency to relapse. The patient should be warned that cessation of symptoms must not be taken as evidence of cure.

EMPLOYMENT OF OVERSEA DOCTORS

In view of the increasing demands on the services of doctors for war purposes, two Orders have been made, under the powers of the Defence Regulations, authorizing the General Medical Council to include oversea doctors temporarily in the *Medical Register* under certain conditions. The first Order applies to doctors qualified to practise in Canada or the United States of America. They must be of British nationality or United States citizens. There is no specific condition as to employment, but the object of the Order is to facilitate their employment in the Emergency Medical Service. The second Order applies to doctors qualified to practise in any part of the British Empire or in the countries of our European Allies, or in Germany or Italy. One of the conditions of registration is that the doctor must be selected either for a medical commission in one of the fighting Forces or for employment in a hospital, institution, or service, not involving attendance in the patient's own home, approved by the Minister of Health (or in Scotland or Northern Ireland the appropriate Secretary of State). The main objects of this Order are (1) to facilitate the employment of medical officers in the allied Forces in the United Kingdom by giving them the privileges of registered medical practitioners, and (2) to facilitate the employment of Dominion and foreign doctors in civil hospitals by giving them the same privileges. The Orders do not affect the operation of the Aliens Acts and Orders. The Central Medical War Committees for England and Wales and for Scotland are compiling a list of doctors likely to be available for civilian employment and qualified for registration under the Orders. Any of these doctors may make a provisional application to the General Medical Council for registration, in order to avoid delay in the final registration when he is selected for employment. Mr. Malcolm MacDonald, the Minister of Health, is sending a circular to local authorities and other hospital-owning bodies drawing their attention to the Orders and advising them to take advantage of the new arrangements for filling vacancies for which British doctors are not available or in order to free British doctors for war service. A similar circular is being issued by the Secretary of State for Scotland.

We print on page 94 of this issue a brief statement on the Nuffield Provincial Hospitals Trust, and an important letter sent by the Minister of Health, Mr. Malcolm MacDonald, to Mr. W. M. Goodenough, the chairman of the Trust.

NUFFIELD PROVINCIAL HOSPITALS TRUST

This Trust was founded by Lord Nuffield in December, 1939, with the object of promoting a proper co-ordination of hospital services throughout the provinces in England, Scotland, and Northern Ireland, by means of full co-operation between the voluntary hospitals and public health authorities, in close consultation with the Minister of Health and the Secretary of State for Scotland. It was hoped that arrangements to this end would be agreed upon a regional basis connected with appropriate hospital and medical teaching centres. It was understood that close contact would be maintained between the Trust and King Edward's Hospital Fund for London.

At the end of twelve months the Chairman of the Trustees has reported to the Minister of Health. The Central Regionalization Council of the Trust has been formed, on which the Provisional Central Council of the British Hospitals Association is represented. A medical advisory council has also been established under the chairmanship of Sir Farquhar Buzzard. An advisory committee of the Trust has been established in Scotland under Mr. Tom Johnston as chairman, with a medical advisory committee under Sir John Fraser.

Discussions on arrangements for regionalization of hospital services have taken place in many important provincial centres with representatives of the public health authorities and of voluntary hospitals. In some of these centres plans for the formation of regional councils are already completed or are well advanced, and it is hoped to set them in motion in many others at an early date. The Trustees expect to be able to consider the question of financial grants to regional councils from the income of the Trust very shortly.

Having been informed of the progress made, the Minister of Health has addressed the following letter to the chairman of the Trustees:

Ministry of Health,
Whitehall, S.W.1,
January 6, 1941.

Dear Goodenough,

I have been keenly interested in my various discussions with you and your colleagues of the Nuffield Provincial Hospitals Trust to learn details of the Trust's present and prospective work, and should like to assure you of my warm sympathy and continuing support in the valuable work that you are doing. The question of post-war hospital policy is one of major importance, and I am sure that the Trust is right in attempting, even during the heat and labour of the present struggle, to focus discussion by bringing together in its regional councils representatives of the various interests concerned with a view to clearing the ground for future action. I can assure you that in the Ministry of Health much careful preparatory thought is being given to this problem, as well as to the wider questions concerning the medical and health services of the nation.

Let me add that I think you are right in concentrating on two points. Whatever may be the proper ultimate hospital service, we should build up from existing organizations, and the first is, therefore, to find the right relation between the local authorities on the one hand and the voluntary hospitals on the other. Both have played a great part in our hospital system in the past and will, I am convinced, make essential contributions to the future. There is, as you know, a variety of ways in which under the existing law a fruitful co-operation between local authorities and voluntary hospitals can be achieved, and I do not doubt that further methods of mutual assistance and co-operation can and should be devised.

Secondly, I am convinced that the problem is one that must be examined on a basis wider than that of existing local government areas and that some form of regional unit will be necessary in designing a system which will make the best use of our existing hospital accommodation and will avoid duplication and waste in making good any deficiencies. The precise manner in which a regional conception of this kind should be fitted into the existing system of local government is in itself a problem calling for most careful, constructive consideration, and I am very glad to know that the local authorities, through their representatives on your regional councils, are taking an active part in the discussions which the Trust has set on foot.

I remember Lord Nuffield telling me on one occasion that it was his early ambition to be a doctor. I am exceedingly glad that he did not realize his ambition. It is not that patients would not have benefited greatly by his skilful attention, but that by turning his great abilities in another direction he has incidentally been able to perform services to Medicine which are unique in their generosity and wisdom, and which place him for ever amongst the unselfish benefactors of mankind.

Yours sincerely,

(Signed) MALCOLM MACDONALD.

W. M. Goodenough, Esq.,
54, Lombard Street, E.C.3.

Reports of Societies

PROBLEMS OF BLAST INJURIES

The Sections of Surgery and of Pathology of the Royal Society of Medicine joined together for a discussion on January 8 on "Problems of Blast Injuries," Mr. J. B. HUNTER occupying the chair.

Prof. S. ZUCKERMAN, after a reference to earlier literature on the subject, described experiments carried out under the aegis of the Research and Experiments Department, Ministry of Home Security, with a view to defining first of all the scale of damage which follows upon exposure to charges of different magnitude. The experiments were carried out on animals, using explosive in paper containers in order to avoid any confusion of results due to missiles.

The effects of blast had been the subject of a good deal of misconception and misstatement. When an explosive detonated, a certain amount of solid substance was converted almost instantaneously into a very much larger volume of gas. When this took place in the metal casing of a bomb a pressure was set up, variously estimated at from 100 to 600 lb. per square inch, as a result of which the bomb casing burst and the gas by expansion imparted pressure to the surrounding atmosphere. The blast wave constituted by this expanding zone of pressure moved extremely rapidly, especially close to the bomb. The wave of increased pressure left behind it a zone of rarefaction, so that behind the advancing front of the blast there was a region of decreased atmospheric pressure. If the amount of pressure were measured according to the distance from the explosion it would be found that close to the bomb the pressure was abnormally high, but that it fell off very rapidly. Taking a large bomb, no very serious pressures from the clinical point of view would be experienced thirty or forty feet away, and at sixty or seventy feet the pressures did not really matter at all clinically, even though they might be sufficient to damage walls and windows.

Experimental Findings

The experiments, Prof. Zuckerman continued, had been carried out on mice, rats, guinea-pigs, rabbits, cats, and monkeys. Different species varied in their susceptibility to given blast pressures. As a general rule it took at least 50 lb. excess pressure per square inch to kill an animal such as a rabbit, and lesions had not been observed with pressures lower than 5 lb. per square inch. Near to the explosion the animals would be found dead within one minute, usually with blood-stained froth in the mouth and nose. Further away, in a zone of lower pressure, the animals would die, as a rule, within twenty-four hours. The clinical features were fairly constant, including air hunger and dyspnoea, but the

animals were nevertheless capable of great physical exertion. Knee-jerks were present, the pupils responded to light, the corneal reflex was in evidence, and hearing did not seem to be very much impaired. Such was the general picture of the animals exposed in the fatal, but not immediately fatal, zone. Further away was a zone in which the animals survived and recovered, and in which they showed no external appearances of injury, though post-mortem examination revealed internal changes.

The changes observed post mortem varied in intensity according to the pressures to which the animals were subjected. The lungs might show minute lesions or severe haemorrhages, which were apparent on the surface and sometimes followed the line of the ribs. In animals which had been exposed to very high pressures the lungs were found to be practically one mass of haemorrhages, with practically no normal substance left. The haemorrhages were not merely pleural; they extended right into the substance of the lung. Occasionally laceration was found, sometimes following the line of the ribs, and with lacerations pneumothorax and haemothorax occurred.

There had been numerous speculations as to how these changes were caused. The view which the experiments substantiated was that the lesions were due to the impact on the body wall of the pressure component of the blast wave. Rabbits were exposed to explosions of hydrogen and oxygen in balloons. When very close to the balloons the lesions were found to be mainly or entirely localized to the side facing the balloon. It appeared to be a direct impact effect, not some general effect through the trachea; if the latter, the lesions would be expected to be bilateral. In another set of experiments one half of the animal was covered with sponge rubber; if the covered side were placed towards the explosion the animal received practically no lesions, but if the covered side were away from the explosion it received many lesions on the side facing the explosion and a few sometimes on the covered side. Pulmonary lesions due to blast were thus at least partly comparable with those due to simple severe falls or blows—of which there were numerous examples in the literature.

No changes have been observed in the heart muscle or in the endocardium, although when sudden death occurred right-sided dilatation was found. Pericardial and epicardial haemorrhage had been observed. Out of several hundred cases all of which had lung lesions, 40% had abdominal lesions also. The intestine was specially susceptible, and haemorrhages had been observed extending around several inches of the gut, rupture of the gut had also been observed. Lesions also occurred in the liver and spleen, less frequently in the kidneys and adrenals, and sometimes in the bladder, particularly around the neck. As for the head and neck, there was bruising around the eyes and in the fascial planes of the orbital cavities. Rupture of the ear drums was observed at high pressures. In monkeys no lesions were observed in the brain itself (in the cortex, mid-brain, pons, and medulla), but in the cord haemorrhages were found around the spinal roots, especially in the thoracic region. Similar but more extensive haemorrhages had been observed in rabbits.

The Clinical Problem

The injuries whose effects he had described were caused by blast alone. A bomb, however, was not a paper container of high explosive. Part of the blast wave was taken up in shattering the bomb casing. The bomb pulled down buildings, sent secondary missiles flying, and in the process of causing these many effects the blast pressure became much decreased. The attenuated blast wave, although it might act like a heavy wind and throw a man against a hard surface, was incapable of causing direct injuries such as he had been describing. A special casualty survey, in which cases had been differentiated according to the circumstances in which each casualty occurred, had made it plain that the danger zone within which the primary effects of blast would be experienced was very limited. There was little likelihood that if one was lucky enough to escape splinter wounds from the detonation of a bomb on the surface one would be killed by the direct effects of the blast of a big bomb further than thirty feet away, and in the case of a small bomb further than, say, about ten feet. Internal lesions, especially in the lungs, which might be observed at further distances were probably not due to blast at all, but to violent falls or the impact of flying or falling masonry.

In general, very few cases of injury due to direct effects of blast had been observed. Sometimes a death had been ascribed to blast when it was in fact due to secondary or tertiary blast effects such as falling masonry. Out of about sixty casualties included in the special casualty survey, post-mortem examinations had been carried out in ten cases. In seven there was lung bruising, but in only one were the circumstances such that the bruising could be ascribed to the direct effect of blast alone. From these observations he concluded that the direct effects of blast alone were rarely the cause of death in air raids; and that when blast injuries did occur they were often mixed up with injuries caused by other agencies.

Some cases of non-fatal injuries due to blast had been seen. One such case was of a man in an anti-aircraft unit who was running to his post when an "alert" sounded; bombs fell and he found himself between three explosions, none further than about twenty-five yards. He was thrown down by the blast, picked himself up, when another bomb again threw him down. Finding himself apparently uninjured, he went to an air-raid shelter, where he started to cough up blood; as he had no external wounds he carried on with his job. Later he had to go into hospital, where he remained for sixteen days, and x-ray films showed shadows in the right base of the lung, which eventually cleared up.

Prof. Zuckerman concluded by again emphasizing that in the case of non-fatal injuries presumed to be due to blast x-ray examination, also an examination of the ear drums, and particularly examination for external injuries, should be made before a diagnosis of primary effects of blast was decided on. Some of the dead brought in after air raids who showed no external sign of injury had died of asphyxiation or of carbon monoxide poisoning. In other cases in which lung injury was found the lesions were usually due not so much to the direct impact of the blast wave as to a blow by some hard substance on the body wall. What actually caused death in such cases—in fact, what caused death in experimental animals subjected to blast alone—was not known, and it was to the solution of that problem that some experiments at the present moment were being directed.

Lung Injuries caused by Blast

Prof. GEOFFREY HADFIELD based his remarks on thirty post-mortem examinations which he and a number of colleagues whom he named had carried out. In eight of these cases there were haemorrhages into the lung without significant external injuries. In four cases there were pulmonary haemorrhages of considerable degree, associated with much saturation of the blood with carbon monoxide. In two cases there were pulmonary haemorrhages and an associated injury not considered to be fatal, such as a fractured limb. In three cases in which the patient had recent haemorrhages into the lung the lung itself showed severe chronic bronchitis and emphysema. Two patients proved to have died from compression asphyxia, and three from asphyxia due to inhalation of finely divided chalk, plaster, and brick dust. Out of the thirty patients who were considered to have died from "blast," eight showed no evidence of a pulmonary lesion. The haemorrhages were frequently deep in the lung and occasionally gave relatively little indication on the surface that they were so extensive. Naked-eye laceration of the lung was not found in the absence of damage to the thoracic wall. No very great degree of rupture of the alveolar walls was found, and very frequently there were large numbers of alveoli whose walls appeared to be quite intact.

The amount of haemorrhage into the lung in these fatal cases varied within very wide limits. He and his colleagues felt that if a patient did recover from the initial explosion bleeding still continued in the lung, so that those who survived showed very much larger areas of haemorrhage than were apparent in those who were found dead. He instanced one victim who had lived for fifty-one hours and had continued to

bleed into his lung during the whole of that time. Prof. Hadfield showed slides illustrating the general and the microscopical appearance of the lung in these cases, and pointed out the significance of the different areas. His deduction again was that bleeding might continue for at least forty-eight hours and reach a considerable degree, causihg consolidation of very large areas of the lung.

After describing in detail the story of the victim who had lived for fifty-one hours after the explosion, and who developed a syndrome which could be said to have been due to generalized capillary congestion of the lesser circuit, with relief of most of his urgent symptoms by venesection, Prof. Hadfield said that, after what Prof. Zuckerman had emphasized, he did not wish to claim that the cases described were due to the pure effects of blast. Seventeen of them, however, showed extensive pulmonary bleeding without significant injury to the thoracic parietes, and one point he wished to make as a result of this post-mortem research was that the primary and essential lesion of pulmonary blast may be widespread dilatation and congestion of the alveolar capillaries. It was worth while considering whether a good deal of the intra-alveolar capillary bleeding was due to diapedesis. If the histological picture were combined with the clinical findings during life, it was rather more easy to explain the latter on the basis of generalized vasodilatation of the whole lung on both sides rather than by the bleeding itself. It seemed that the major clinical manifestations shown by these patients were due more to this enormous capillary dilatation of the lung than to actual bleeding, which might well be an expression of the vasodilatation.

Prof. Hadfield concluded by saying that he felt that his contribution to the discussion, founded as it was on human material, was rather a premature one. What he had said was founded on a very short experience, but the evidence did point to this single fact—that following exposure to detonation of a high-explosive bomb bleeding into the lung could continue for a period of days. This must, of course, have an influence on treatment, and patients should be kept immobile and treated as for haemoptysis.

General Discussion

Dr. J. N. O'REILLY said that in three cases which he had been investigating one clinical point had emerged—that within forty-eight hours in two of them and within four days in the other the cases had apparently become those of ordinary clinical lobar pneumonia. Another point was that five patients belonging to the same "incident" were brought in with the appearance of acute abdominal catastrophe—rigid abdomen, pain, and so on—and two of the cases were sufficiently serious to require surgical intervention; but nothing was found except a few minute subserous haemorrhages. Dr. J. M. ALSTON asked whether Prof. Zuckerman's work had gone far enough in the direction he had indicated to decide whether the animals which survived the shock experiments showed the lesions of pseudo-pneumonia, as Dr. Hadfield had suggested. Dr. BERYL BARSBY had seen two cases of injury unquestionably due to blast in which there was spontaneous haemothorax, with *x*-ray evidence of blast on the other side and ruptured spleen

Prof. ZUCKERMAN, in replying on the discussion, said that he had seen no evidence of haemorrhage continuing in the lungs of experimental animals as a result of exposure to blast, although lesions were often better marked in animals which survived for some time than in animals killed outright by blast. He added again that he was not convinced, without knowing in detail about the circumstances of injury, that haemorrhagic lesions in the lungs which were observed in air-raid casualties were due to blast alone. The possibility that such lesions might in some cases be due to violent falls or the impact of solid bodies should, he felt, also be borne in mind.

Two hospitals for casualties for the British Forces in the Middle East are to be established in South Africa at the request of the British Government. They will be situated near Johannesburg and Port Elizabeth.

Correspondence

Epidemic Influenza

SIR,—The letter by Dr. William Hartston on the above subject (December 21, p. 878) accuses me and my colleagues at the National Institute for Medical Research of retarding a simple understanding of the disease "influenza." As the clinical member of this team of workers until recently, I am sorry if our work has retarded a clear understanding of "influenza" by any of my fellow clinicians. However, it is my opinion that at the present time any simple understanding of the syndrome of clinical influenza is an illusion.

In any investigation of a clinical condition it is necessary to proceed from the known to the unknown. Thus in 1937 the ferret-pathogenic virus now termed "influenza virus A" (*Lancet*, 1940, **2**, 413) had been recovered in various parts of the world only from outbreaks of respiratory disease occurring during widespread epidemics of influenza in the community. It had not been recovered from sporadic cases of influenza, nor from several localized outbreaks of respiratory disease occurring in schools and Service institutions. At that time clinical and epidemiological differences were detected between the latter outbreaks (then termed "febrile catarrhs") and the one widespread epidemic of virus A influenza which had been studied (Medical Research Council Special Report, No. 228, 1938). Wilson Smith, Andrewes, and I therefore chose to refer to the ferret-pathogenic virus as "epidemic influenza virus" to avoid confusion with these other diseases of unknown aetiology. The care with which this term was used by us on all possible occasions was apparently lost on Dr. Hartston, who now pleads that we had failed to recognize the existence of an *endemic* clinical influenza not due to any known virus!

In 1939 there occurred in Great Britain an epidemic of influenza which differed from that of 1937 in having a lower incidence of pneumonia (*Lancet*, 1940, **1**, 205). During this epidemic the ferret-pathogenic influenza virus A was not absent, as Dr. Hartston states, but evidence of its presence as an infecting agent was found in approximately 30% of cases only. At the bedside I found it impossible to distinguish cases which would yield influenza virus A from those where the virus was not demonstrable. The investigations of Dr. Wilson Smith and Dr. Andrewes upon the cases of clinical influenza which were virus-negative on ferret test led them to suspect that another virus unrelated to influenza virus A was responsible for the clinical condition. All attempts to demonstrate this hypothetical virus, however, were fruitless. The investigation of future outbreaks will doubtless decide whether epidemics of influenza are at times aetiologically diverse, as was suspected in 1939.

Meanwhile, Francis in New York (*Science*, 1940, November 1) has succeeded in recovering a virus weakly pathogenic for the ferret but serologically quite distinct from influenza virus A from patients during an outbreak of influenza in 1940. This virus has been christened by him "influenza virus B," and its existence reveals clearly the aetiological diversity of the clinical condition "influenza." It is probable that we are only upon the threshold of knowledge concerning the pathology of epidemics of influenza. In the present circumstances it seems to me unreasonable to demand a clarification of the term "influenza." We must await further knowledge, and I would plead for patience on the part of those clinicians who find the ways of research workers laborious and even confusing.

In conclusion, I do not propose to criticize Dr. Hartston's suggestion for forecasting influenza pandemics, because we have as yet no certain knowledge of the causation of pandemic influenza.—I am, etc.,

C. H. STUART-HARRIS,
Major, R.A.M.C.

Jan. 4.

Medical Planning Commission

SIR,—I wish to congratulate the Executive Committee and the Council on the personnel of the Medical Planning Commission. I am not quite clear as to the powers and functions

of the body, and being jealous of the rights of ordinary members and democratic ruling of the Association I am anxious to be told what these are.

The terms of reference are quoted as being, "To study wartime developments and their effects on the country's medical services, both present and future." Did the Council of the Association find this too big a job? In my opinion it should not have been had the Representative Body and the Branches elected their members with sufficient care. However, the Council has, without any reference to the Divisions and Branches, appointed the Commission, and since we as a Representative Body gave these powers to the Council we can have no grounds for criticism.

Will the Commission report direct to Council? Will the Divisions and Branches have a chance to study and if necessary criticize its findings? I understand that the real work will be done in committees set up by the Commission itself. In what way will the duties of these committees differ from those of the committees elected by the Representative Body in Aberdeen in 1939? Is there any new aspect of medicine which does not come within the purview of those committees?

Your leading article (January 4, p. 19) says, "War has thrown up into sharp relief the deficiencies of our peacetime system of administering relief to the sick and of promoting and maintaining the health of the people." If the report of this Commission is endorsed by the members as a whole, will it not prove that the war has also shown that within the Association our present system of self-government and election is also deficient, since it was found that such an important work was beyond those we elected?

The task which is set for the Commission is great and necessary. It is obvious to many of us that a change will be necessary after this war is over, but this is not a result of the war; it has been on the medico-political horizon for many years; the war has made some people see it more clearly. Mr. Walker's admirable speech at Aberdeen in July, 1939, though not covering the whole ground, made many of us who talked on this subject outside the meeting realize that we all agreed on at least one principle—namely, that a change, and a radical change, was necessary.

It would be most desirable that, when the Commission's report is presented, before adopting it or any part of it the Council should send it to the Branches and Divisions and also find a way for the Service members to discuss it, for they will be concerned very materially when they return to civilian practice. The correspondence columns, which are at the moment practically the only medium of discussion, are not adequate for the purpose of discussion on a problem of such magnitude.—I am, etc.,

Yardley, Jan. 7. ARTHUR BEAUCHAMP

*** The Secretary of the British Medical Association states that Dr. Beauchamp may rest assured that the Commission will report direct to the Council of the Association, and that Divisions and Division Branches will have a chance to study and, if necessary, to criticize the findings of the Commission.

SIR,—The problems that will face England at the end of the war will be many and great. It is possible, I suppose, to return to the pre-war medical position, but even if this is possible it should be refused, for the only chance of a better medical service will be to cut away completely from the old order.

Already before the war the B.M.A. had foreseen coming trouble and had tried to put its house in order, but unfortunately the changes suggested were not radical enough. Now the Commission faces an enormous task—a task with which no preconceived ideas should be allowed to interfere. The background to all these difficulties is, first, the impoverished state of our country, and, secondly, the unsatisfactory nature of pre-war medical practice.

The problems with which I wish to deal in this letter are two. First there is the problem of the return of evacuated medical men to their areas before the return of the population, and the consequent financial suffering of all; surely the Government should be pressed at an early date to allow of only gradual return and to make financial arrangements to tide over this difficult period. Secondly there is the problem of voluntary hospitals in evacuated districts at the end of the war: the impoverishment of the much smaller population will make it difficult, if not impossible, to raise sufficient funds to maintain these hospitals, and it seems to me that only State aid can possibly save our hospitals.

I am convinced that the future of medical practice in England will be a full-time State medical service with a pension at 60. Two difficulties will have to be faced. The first is the prevention of lack of initiative due to the sense of security afforded by the Civil Service, and this danger will be even more prevalent in the medical service. The remedy is to have promotion, to a considerable extent, dependent on the success of the practitioner. The second will only exist at the beginning of the service, and is caused by the fact that the purchase price of the practice is, often enough, the only capital the general practitioner can save for his children. This capital should be repaid, and in the case of the medical men of 60 or over who are compelled to retire on a pension their capital could be repaid by capitalizing part of their pensions.

These are but some of the ways by which we hope to obtain a medical service satisfactory both to the nation and to the medical profession. The Commission must achieve success, for if this self-appointed Commission fails, never again will the medical profession have a chance of setting its house in order. —I am, etc.,

Felixstowe, Jan. 6. P. L. GIUSEPPI.

Transplacental Tuberculosis and Transplacental Melanomatosis

SIR,—Dr. Monica Davin-Power's case (January 4, p. 13) appears, as she claims, to be a genuine example of transplacental tuberculous infection, although the placenta was not examined, and one may remember that Schmorl declared that as many as 20,000 sections might have to be gone through under the microscope before tuberculous lesions, even when really present, could be found in a placenta.

The study of the very rare published cases of proved transplacental tuberculous infection[1] throws light on the possible transplacental infection of the foetus in other microbic diseases. To my mind it also suggests that in extremely rare cases a woman suffering from disseminated metastases of some malignant neoplasm might become pregnant. If so, one or more metastases might occur in the placenta, and might "grow through" the placenta into the foetal circulation, tumour cells thus passing via the umbilical vein to the foetal liver. The child might then be born apparently free from disease. After seven months or so, on examination its liver might be found irregularly enlarged, and later on it might begin to lose weight, and, with increasing cachexia, die nine or ten months after birth, with multiple malignant neoplasms, mostly in the liver. Nevertheless, I know of only one recorded case in which this really was proved to have happened. The case in question was one of malignant melanomatosis, which I published conjointly with my colleagues Dr. E. Schwarz and Dr. R. Hellenschmied in the *Lancet* in 1930 (**1**, 537). The infant's mother had died three months after childbirth with visceral and subcutaneous metastatic melanomata. Mr. Eardley Holland was fortunately able to assure us that the placenta was huge and black, and proved on examination to be infiltrated with masses of melanotic growth. The child's liver, now in the museum of the Royal College of Surgeons of England, was demonstrated by us on February 28, 1930, at the Royal Society of Medicine. The nature and whole course of the neoplastic disease in mother and child were proved to the hilt.—I am, etc.,

London, W.1, Jan. 6. F. PARKES WEBER.

Sunlight Treatment

SIR,—One is somewhat surprised to see that the letter published under this title in your issue of December 21 (p. 883) is signed by Dr. Albert Eidinow. As a whole it conveys the impression of decrying actinotherapy in general and the mercury vapour lamp in particular—an impression which I am sure Dr. Eidinow did not intend to convey, and which no user of actinotherapy would wish to leave on record unexpunged.

[1] Weber, F. P., "Congenital Tuberculosis—A Survey," *Brit. J. Child. Dis.*, 1916, **13**, 321, 359.

On one point of fact Dr. Eidinow appears to be gravely misled in his statement: "Unfortunately the therapeutic value of the rays of the mercury spectrum is derived from the ultra-violet rays of short wave-lengths—from 2,970 Ä.U. to 2,500 Ä.U. These rays are completely absent in sunlight as received at the sea level." This statement correctly describes a low-pressure mercury discharge tube on Geissler principles (what our American friends term a "cold quartz lamp"), but is quite at variance with recent determinations of the output from a high-pressure mercury arc as commonly used by electro-therapists in this country. The radiation from such a source —that is, from the arc itself (disregarding heated metal reflectors)—is distributed as follows:

A. Non-solar erythema-producing ultra-violet from 1,850 to 2,800 Ä.U.	18.5%
B. "Dorno" rays—that is, erythema-producing ultra-violet, 2,800 to 3,200 Ä.U., corresponding to mountain sunshine	20.3%
C. Inactive (solar) ultra-violet, from 3,200 to 4,000 Ä.U.	15.9%
D. "Visible" radiation	35.0%
E. Infra-red	10.3%

Among these groups the "Dorno" rays are much the most important in all those therapeutic actions which are associated with the production of erythema; the radiation shorter than 2,800 Ä.U. has much less erythema-producing power, and is largely absorbed in the outermost layers of the skin. It is perhaps worth expanding this point, since it was once not uncommon for writers to speak in terms of "short-ray technique." As Dr. Eidinow well says: "No simple lamp has as yet been designed which emits rays of light containing similar intensity and wave-length to the sun or sunshine." Indeed, physicists tell us it is technically impossible for any lamp to emit radiation similar to sunshine, since no substance on earth can be made to burn at the solar temperature. Yet it would be totally erroneous to ascribe the therapeutic value of the mercury arc solely to rays which are outside the solar spectrum.

Sixteen years ago I stated my opinion that accurate prescribing in actinotherapy was only possible with artificial sources, and provided that an ultra-violet lamp gives the required results, as the mercury vapour arc abundantly does, one is not disposed to care whether it resembles sunlight closely or otherwise. That the short (non-solar) wave-lengths have some value is, however, substantiated by too many clinical observations to be doubted to-day. One of the most recent and interesting tests in this connexion was made by Kovacs (1937), who irradiated two groups of patients suffering from secondary anaemia with (*a*) the complete quartz mercury vapour spectrum, and (*b*) equal amounts of radiation from the mercury arc so filtered that the shorter rays were eliminated. In both groups the production of haemoglobin was increased, but the rate of increase was found to be greater when the complete spectrum was used. Widely different from sunshine in a spectral sense, the mercury vapour lamp is clinically valuable because of its emphasis on the important "Dorno" rays, so deficient in our climate. If its additional (non-solar) radiation adds to its therapeutic value we clinicians may accept that and be grateful.

On the subject of technique Dr. Eidinow's letter leaves the impression that the only dose which is valuable for increasing immunity and resistance is the minimal erythema dose administered on a limited skin area. While I have gratefully quoted Dr. Eidinow's conclusions on this restricted-area dosage in several editions of my book, I equally emphasized—and do so to-day on much greater evidence—the value of exposing the whole body to ultra-violet radiation in minimal or sub-minimal erythema doses. This technique of restricted skin-area doses for tonic effect—as distinct from counter-irritant local actinotherapy, which is a different matter—was originated by Dr. Eidinow fifteen years ago, based upon his experiments on rabbits. He has proclaimed it consistently ever since, and so it has doubtless been extensively tried; yet despite the very widespread use of actinotherapy to-day in public health work, in the Services, and in private practice, the method of general irradiation for tonic effects continues to be the method of choice. Dr. Eidinow has therefore fallen into a very grave *lapse dixit* in his closing remark: "Beneficial results will only be obtained when dosage is accurately controlled by a technique similar to that which I have described as 'short-wave therapy.'" Nobody could support either the terminology or the assertions of this sentence. The term "short-wave therapy" is, of course, now definitely kept for a different form of electro-medical treatment. The beneficial results follow consistently after quite other techniques, not only in the treatment of disease but in what I have described elsewhere as the treatment of health—that is, the use of artificial sunlight for the keeping of health and the prevention of disease. I followed with very close interest the first practical and very successful experiments in this connexion at a colliery and a theatre respectively many years ago, and so can see nothing but good in the very widespread use of tonic artificial sunbaths to-day. As a means of maintaining health among overworked munition makers, overtaxed members of the fighting Forces, under-rested shelter sleepers, and so forth, I can conceive of no other single-measure which could be so beneficial.—I am, etc.,

F. HOWARD HUMPHRIS.

Watermouth Castle, N. Devon, Jan. 2.

Haemorrhagic States with Snake Venom and Lecithin

SIR,—It was with particular interest that I read the article by Prof. L. J. Witts and Miss Felicity C. G. Hobson (December 21, p. 862), since I published recently a paper[1] showing that Russell-viper venom may with advantage be substituted for tissue extract in Quick's method of prothrombin estimation.

I find it difficult to understand the authors' contention that "if venom is used instead of brain extract to measure prothrombin in the Quick test it must be fortified by the addition of lecithin." Their figures do not support this statement, since the values they obtained using Quick's test lie closer to those obtained by the use of venom alone than to those given for venom plus lecithin. This can be clearly seen by plotting their results with Quick's test in Fig. 1.

But an essential condition of Quick's test for prothrombin is that an *optimal* amount of thromboplastin must be added to the plasma. The authors added to 0.1 c.cm. of plasma 0.1 c.cm. of Russell-viper venom in a dilution of 1 in 50,000, whereas I have shown that the optimal dilution of venom in this test is approximately 1 in 10,000. If more dilute venom is used longer clotting times are obtained. The failure of the authors to use an optimal concentration of venom makes it impossible to assess their results with any accuracy. Moreover, they state that in disease of the liver the clotting times with Quick's reagent and venom plus lecithin run parallel. Actually a comparison was made in only one case apart from the patient with "treated jaundice." Lecithin undoubtedly seems to have a potentiating effect on the coagulant action of Russell-viper venom, but the authors have not proved that its use in a test for prothrombin deficiency is desirable.—I am, etc.,

Aberdeen, Jan. 8. HAROLD W. FULLERTON.

Oxygen Therapy

SIR,—It is well on forty years since Pembrey and Beddard first mooted the use of oxygen as a therapeutic measure. To the public its use is associated with impending dissolution, a frantic call for oxygen in a dying relative, the incessant bubbling bottle at the bed of the pneumonic patient, and the inevitable final words of the bulletin presaging the death of some notable personage: "Oxygen is being administered." Even the doctor himself, pardonably a little baffled by the complexity of some of the physiological principles involved, seems reluctant to use it except in some of the final stages of respiratory embarrassment.

Within the last few years, especially with the simplification and perfection of the mask, oxygen therapy has become a measure not only for the heaving struggling chest but also for the living, struggling cell far from this scene. Its great value in shock is accepted, but its hesitant use still indicates that it is reluctantly appreciated. In such conditions as abdominal distension and thyrotoxicosis and post-operatively as a routine following gastric operations it has proved itself. It is by its local effects that it now gives promise to play its greatest

[1] *Lancet*, 1940, 2, 195.

role. We know of it as a valuable weapon in peripheral vascular disease. We know that in any injury—whether it be burns, the bomb splinter, the surgeon's knife, the trauma of the stitch—there must be a number of cells whose survival depends on whether they encounter circumstances most favourable to repair. Any bruised tissue suffers from oxygen lack, and the importance of this is enhanced by the fact that trauma in the neighbourhood of a vessel results in spasm, which limits further the blood supply. The maximum amount of oxygen that can be carried in that now trickling stream is, therefore, of prime importance. By the inhalation of pure oxygen it is known that the oxygen in solution in the plasma, which is normally 0.3 c.cm. per 100 c.cm. of blood, is raised to 2.2 c.cm. The oxygen in combination with haemoglobin is simultaneously raised from 19.2 c.cm. to 20 c.cm. There is thus produced a total increase of arterial oxygen from 19.5 c.cm. to 22.2 c.cm. per 100 c.cm. of blood, an increase of nearly 15%. Of even greater importance than the percentage increase in the amount of oxygen is the rise in its partial pressure in the blood, for it is this that determines its availability to the tissues. In fact, Boothby has shown that in the shocked patient with his low venous oxygen the partial pressure of oxygen in the capillaries may be raised from 14 to 21 mm. Hg—a rise of 50%—by the inhalation of pure oxygen alone.

It is all too common for cyanosis to be regarded as the prime indication for oxygen therapy. In fact, cyanosis does not occur until there is at least 5 grammes of reduced haemoglobin in 100 c.cm. of blood. It follows, therefore, that in haemorrhage, shock, and anaemic states oxygen want may be present long before there is sufficient reduced haemoglobin to give a visible external indication as cyanosis. This established fact, which is of the utmost importance, has not in the past been sufficiently stressed.

Despite reassurance the patient, as he dons the mask, feels that he "must be bad." He is apprehensive, afraid to go to sleep, and is often anxiously restless. The use of oxygen is often postponed, even by the doctor, as he himself is "anxious not to alarm the patient." The education of the public that oxygen inhalation is a therapeutic measure of great value and not a forlorn hope is, therefore, an urgent need.—We are, etc.,

SOL. M. COHEN.
Dartford, Jan. 10. WILLIAM W. MUSHIN.

Adie's Syndrome

SIR,—In the annotation (January 11, p. 58) it is implied that the syndrome referred to under the above title was first identified by Adie. Sixteen years ago I published an account of the condition with illustrative cases at the congress of the Ophthalmological Society of the U.K. (*Trans. ophthal. Soc. U.K.*, 1924, **44**, 38). Adie's first communication was before the same society some six or seven years later: he extended the observations in several particulars, but added no essential point. He suggested the title "myotonic pupil," which has been accepted and is perhaps more appropriate than the more cumbrous one of "pseudo Argyll Robertson" which I had applied to it.

My own notes and books are no longer available, so that I cannot here give the exact references, but I believe I stated them accurately in a previous letter on the same matter published in the *Journal* about six years ago. I may perhaps quote the summary of my observations from the second edition of *Medical Ophthalmology*, which was published fifteen years ago (p. 136). (1) The contraction with convergence, and dilatation when convergence was relaxed, were characteristically slow. (2) None was associated with paralysis of accommodation. (3) All dilated freely with mydriatics. (4) In four out of seven cases they were uniocular. (5) None of the cases was associated with syphilis. (6) The knee-jerks were present in every case. (7) In no case was there evidence of parasyphilitic or any other general nervous disease, even after so long as thirteen, thirty-six, and forty years in three cases I afterwards commented on its preponderance in the female sex.

It will be seen that the condition was recognized and described a number of years before Adie's report of it.—I am, etc.,

Bemerton, Salisbury, Jan. 12. R. FOSTER MOORE.

Some Nutritional Problems of War and Peace

SIR,—In your report of my recent lecture to the Pharmaceutical Society (1940, **2**, 913) I am quoted as having said: "Calcium was known to be essential, but not its quantities. . . ." The report is at fault. Not only did I not make this remark, but I have, along with Prof. Drummond (*J. Soc. chem. Industr.*, 1940, **59**, 37), published our joint views as to marginal and optimal daily requirements for this element. We have there expressed the opinion that for the "average" man of about 10 stone weight the respective figures are 750 and 1,500 mg.—I am, etc.,

Greenford, Middlesex, Jan. 6. A. L. BACHARACH.

The Mobile Unit in Action

SIR,—May we crave your indulgence in asking you to publish yet another letter regarding this important subject. The tendency of the majority of your recent correspondents has been to disparage the use of these units, but close scrutiny will reveal the facts that either your correspondents' experience has been extremely limited or else there has been some gross lack of co-ordination with Control or the other allied services.

We are in charge of the two mobile units attached to the metropolitan borough of Southwark. During the months of September and October last we attended a total of forty-four incidents, excluding the incidents attended only by doctor and nurse. Our average is, therefore, 22 as compared with the average for the country of 4.4. The total number of casualties dealt with was over 200, and in one major incident the two units working side by side dealt with forty casualties, apart from giving morphine to five trapped persons. You will therefore readily appreciate the fact that in this metropolitan (not rural or urban) district the mobile first-aid unit is held in high esteem.

May we also draw your correspondents' attention to another feature which they have apparently overlooked—namely, the "insurance" value of the unit. We are still in the early days of aerial warfare, and all too often one reads of hospitals, first-aid posts, and ambulance stations being destroyed. The mobile unit is invaluable inasmuch as it will in an emergency form the nucleus of an improvised hospital (in conjunction with the mobile surgical unit): it can replace a first-aid post at a moment's notice (we have already had personal experience of this): and, finally, in the event of ambulance transport being overworked or destroyed the unit will go to the casualties instead of their being sent to hospital or a first-aid post.

In view of our extensive experience we would respectfully suggest that the mobile first-aid units are invaluable in the A.R.P. scheme, not only because of what they can do when properly used, but also because of what they might do should the emergency arise—as possibly it might.—We are, etc.,

M. M. SCOTT
London, S.E.17, Jan. 6. H. C. DUNDON.

SIR,—I have been very interested in the letters which you have published recently giving your readers' views and experiences on mobile van duties during air raids. I thought you might be interested in our experiences in Sheffield during the recent raids here.

The van was staffed by nurses and two doctors. The idea of the van was to establish a first-aid post should the local one be destroyed, or to perform any urgent operation such as an amputation should this be necessary to free a person trapped by fallen debris, etc. Our first call was to a case of two casualties at a point distant about two miles from the hospital. We arrived to find that they had been sent to the F.A.P. At the post we were told that one case had been sent to hospital by ambulance and that the other was being given shelter following suture of a simple laceration. The next call was an urgent one to the centre of the city to deal with many casualties. After driving through water, broken tram-wires, and making detours to get past blocked roads we reached our destination to find a ring of blazing buildings and not a person in sight. Bombs were dropping all round, as the light from the fires was so good that one could have read a newspaper. We finally discovered a group of wardens vainly trying to rescue someone trapped under

about twenty tons of debris. We returned, narrowly missing driving into an unexploded bomb crater on our way back. Later we were again called out to a man trapped in a fallen building. This turned out to be genuine. The man was caught by the foot with fallen masonry. We were asked to wait for fifteen minutes while the rescue party attempted to free him. This they successfully accomplished, and the man was sent to hospital by ambulance. The "all clear" went in the middle of the last case.

It seems to me that as it is impossible to verify calls during a raid a mobile van is simply at the mercy of any nervous individual who cares to phone up the hospital direct or the police station. The only sensible solution would appear to be that no mobile unit should be sent out until after the raid is over, as the extremely slender chance of their being able to do any good is completely outweighed by the risks encountered. I may say that it is an experience never likely to be forgotten by any taking part in it.—I am, etc.,

Sheffield, Jan. 11. R. E. MCLACHLAN.

SIR,—Although a mobile first-aid unit under the present circumstances has limited uses if it is not superfluous, there are, I think, three occasions on which a well-equipped mobile resuscitation unit can be of great service. The first two have frequently been encountered round here in the last four months. (1) For casualties under buildings who have been reached by the rescue party but who are still pinned down by the wreckage, fallen beams, etc. (2) For those who have been under wreckage for a long time and come out in such a shocked condition that it is imperative for them to be treated before an ambulance journey can be undertaken. (3) For small towns which suffer a concentrated attack and whose hospital facilities are inadequate to deal with the volume of casualties.

An ambulance with the upper stretchers removed can quite easily be fitted out with the complete apparatus for treating shock. One patient at a time is normally treated in it, but if necessary two can be managed. In the ambulance here we carried eighteen bottles of plasma and a corresponding number of transfusion sets, with half a dozen blood bottles full of sterile citrate for washing out apparatus, and a cutting-down set and accessories. This apparatus could easily be used in the ambulance, and the simplicity of the E.M.S. transfusion set makes it ideal for taking into wrecked buildings and using under difficult circumstances. The morphine is carried in rubber-capped bottles for use with a syringe, and a supply of tubunics is also kept. A 100-cubic-foot cylinder of oxygen was kept under the stretcher for use in the ambulance, and in addition a small portable cylinder was taken for use outside. The interior of the ambulance was heated, and we carried hot tea, rugs, hot-water bottles, and blocks for raising the foot of the stretcher. In addition the usual first-aid surgical equipment was of course carried.

With this type of unit it is only necessary to be called out when conditions (1) and (2) are met with, and not for ordinary casualties, where the quicker they reach hospital the better. And, in addition, one often has several hours' notice as to when the trapped casualties are likely to be reached. Transfusions can be sometimes performed under the wreckage, and those suffering from prolonged exposure can be treated at the earliest possible moment in the ambulance (very often long after the raid is over).

In the case of emergency (3) a large number of bottles of plasma or blood, transfusion sets, blankets, hot-water bottles, and a personnel of half a dozen can be ready to start at an hour's notice to equip and manage a resuscitation ward, where needed, or to help in an overworked hospital.—I am, etc.,

Guy's Hospital, S.E.1, Jan. 9. PETER H. CARDEW.

Second Attack of Cerebrospinal Fever

SIR,—The following brief statement (and request for information) may be of interest to readers.

In February of last year a boy aged 16 was notified as a case of cerebrospinal fever. To-day a report has been received that he is again suffering from this disease. Dr. Edwards of the County Laboratory confirms that on both occasions meningococci in culture were obtained. Dr. Cowan last year kindly supplied me with notes as to the treatment. Serum was given in the early stages combined with sulphapyridine. (Clinical notes and full bacteriological reports have not been recorded in order to save space. They are available if required.)

May I ask: Are two attacks as unusual as my limited experience suggests, and does the prompt use of sulphapyridine prevent the development of immunity?—I am, etc.,

H. B. BINKS,
Stafford, Jan. 6. Medical Officer of Health.

Unification of Shelter Control

SIR,—Dr. Margaret Lowenfeld (January 4, p. 28) accuses me of quibbling about the word "dictator," but, unfortunately, it was used in an editorial heading. It is important that we do not use this sinister term when something else is intended. That the unification of the medical services of the metropolitan area is an urgent necessity no one would deny, and it is what we *must* press for. To believe that either the medical profession or any other body can solve their problems by appointing a "directing mind" or dictator with the same "full authority to act" as the Government already possesses through the Orders in Council is fallacious. Why are the practical and admirable suggestions concerning organization as outlined by Dr. Lowenfeld and other correspondents not immediately utilized?

As numerous solutions of this problem have been suggested by both medical and lay bodies and have hitherto not been put into practice, the medical profession is now confronted with the necessity of deciding where the responsibility lies.—I am, etc.,

Pontypool, Jan. 6. A. S. JARMAN.

Proprietary Names for Drugs

SIR,—In three consecutive issues of the *Journal* (December 21, p. 875, annotation on Rationalization of the British Drug Industry; *Supplement*, December 28, p. 59, Mr. E. Lewis Lilley's article on N.H.I. prescribing; and January 4, p. 33, Dr. R. Forgan's letter) reference has been made to the difficulties created for the medical man by the multiplicity of proprietary synonyms for medicinal substances. But no solution is anywhere suggested for what, after all, is becoming an intolerable state of affairs.

While it is true that many of the larger firms when marketing official substances under proprietary names usually indicate on their packings the English official name of their product, this practice is not sufficiently general to be helpful. But the whole situation could be greatly simplified if the provisions of the Therapeutic Substances Act and Regulations respecting the naming of the substances there dealt with were made generally obligatory—that is, that underneath the brand name on the label must appear the English official name of the substance in letters equally large. This could be extended to include all preparations where the chief active ingredient was an official substance.

A difficulty, of course, arises when it comes to dealing with important substances not yet official, and it is here too that more than simple questions of nomenclature would have to be considered. Is it not high time that in this country we had a body comparable in its aims and functions with the Council on Pharmacy and Chemistry of the American Medical Association and working in close collaboration with the parent body? A substance, whether protected by patents or not, accepted for inclusion in "New and Non-official Remedies" and/or the corresponding British publication could then have chosen for it, by the accepting body or bodies, a "standard" name, which, for the purposes of labels, circulars, and advertisements, would have the same status as an English official name.

The situation would then be such that similar provisions would apply to the use of proprietary names for both "official" and "accepted" substances. The obligatory use of the English official or standard name in all instances would have manifest advantages over an obligation to give only, in addition to the trade name, the chemical description of the product, for this, in many instances nowadays, is too complex to convey anything to the average practitioner, and, in any event, is capable

of such manipulation and variation in its expression as to give more than momentary difficulty even to a chemist

The operation of such a scheme as suggested here would, while maintaining some at least of the supposed advantages of the trade name, remove nearly all its manifest disadvantages. Thus, in the case, say, of an important new chemotherapeutic substance discovered and marketed by a single firm under a trade name, the firm would have all the advantages accruing from both their monopoly and their use of this name, but the medical profession would presumably be so familiar with the standard name by the time the product became official that it would not be worth the while of any firm to devise a new one. The method would then perhaps be generally adopted that, while the firm which gave the world "M & B 693" would continue to give it, the firm of Blank would be content to offer sulphapyridine (Blank), and everyone, including the poor pharmacologist who has to teach about these things, would be satisfied.—I am, etc.,

Robert Burns's Diet

SIR,—In praise of the Scottish ploughman's fare Dr. S. Watson Smith (January 11, p. 63) states that "on this diet Robert Burns, *that prince among poets*, was nurtured, and subsisted all his days." As Burns died at 37 Dr Smith can hardly be accused of overstating his case.—I am, etc.,

M. NEWFIELD.

Universities and Colleges

UNIVERSITY OF LONDON

Sir Ernest Graham-Little, M.P., has been unanimously re-elected chairman of the Council for External Students of the University of London for the year 1940–1.

ROYAL COLLEGE OF SURGEONS OF ENGLAND

At a meeting of the Council of the Royal College of Surgeons of England, held on January 9, with the president, Mr. Hugh Lett, in the chair, Surgeon Rear-Admiral G. Gordon-Taylor was appointed Bradshaw Lecturer and Mr L. R. Braithwaite Moynihan Lecturer for 1941.

Mr. Lett was congratulated on having received the honour of a baronetcy.

Dr. Gilbert Orme was reappointed as representative of the College on the Council of the Queen's Institute of District Nursing.

The Hallett Prize adjudged on the result of the recent Primary Fellowship examination was awarded to Jenkin Dillwyn Thomas Jones of the University of Durham.

The posts of the three house-surgeons at the Palmerston North Hospital, New Zealand, were recognized for the six months' surgical practice required of candidates for the final examination for the Fellowship.

The date of Mr. R. E. Smith's Hunterian Lecture on the undescended testicle has been changed to January 23. The lecture will be delivered at the Royal Society of Medicine (1, Wimpole Street, W.), as will all the others announced in this column on January 11 (p. 67). This was omitted by an oversight from the original announcement.

Diplomas

Diplomas in Psychological Medicine were granted, jointly with the Royal College of Physicians of London, to the following candidates:

Margaret MacK. Methven, G. C. Rae, B. A. MacG. Williamson.

L. S. Powell and R. L. Dunlop (*J. Kansas med. Soc.*, 1940, **41**, 432) record two cases of visual disturbance complicating mumps. The first was in a boy aged 11 years who three weeks after the onset of mumps developed severe optic neuritis as well as labyrinthitis. Some improvement took place, but a veil about the vessels at the optic disk and slight pallor of the nerve head persisted. The second case also occurred in a boy aged 11 years, who in convalescence from mumps developed a mild papillitis with paralysis of accommodation. Complete recovery took place.

Obituary

HERBERT TILLEY, M.D., F.R.C.S.

Consulting Surgeon, Ear, Nose, and Throat Department University College Hospital

As announced in our last issue, Mr. Herbert Tilley died on January 6, aged 74. He was born at Shepton Mallet, Somerset, and was educated at Queen's College, Taunton, and University College Hospital. He graduated M.B., B.S. of the University of London in 1890, took the M.D. in the following year, and was granted the diploma of F.R.C.S. in 1898. He was consulting surgeon to the ear, nose, and throat department (Royal Ear Hospital) of University College Hospital and laryngologist to the Radium Institute. In 1931–2 he was president of the Medical Society of London and in 1932 was elected a Fellow of University College. He joined the British Medical Association in 1895, was secretary of the Section of Laryngology and Otology when the Association met at Portsmouth in 1899, was vice-president of the same Section at Ipswich in 1900, and was president of the Section of Laryngology at the London Meeting in 1910.

The passing of Herbert Tilley will evoke profound regret among a large section of the profession, for he occupied during many years an outstanding position in British laryngology. He first practised in Hampstead, an experience which he always regarded as of great value, but soon became interested in laryngology, and was appointed to the staff of the Throat Hospital in Golden Square. When a department for diseases of the throat and ear was established at University College Hospital he was appointed to take charge of it, and it was to the welfare and development of that department that he thereafter devoted his time and energy unsparingly. The department, which eventually became amalgamated with the Royal Ear Hospital and, by the liberality of Geoffrey Duveen, is housed in a carefully designed building adjacent to University College Hospital, was his special pride. He took up the study of laryngology at a period of very active progress, when development was proceeding in almost every direction, and his own contributions were mostly in connexion with the pathology and surgery of the accessory sinuses of the nose. He wrote much about this, especially in the later editions of a book of which the first had come from Dr. de Havilland Hall, whilst the fourth and last edition, so much revised and expanded as to be almost a new book, came from himself alone. Finally, in 1934, he gave a final exposition of his views on the pathology of sinusitis in a Semon Lecture, which was filled with original clinical observation and wisdom. This work established his reputation both on the Continent and in the United States, so that besides having the unusual distinction of being president of both the Section of Laryngology and the Section of Otology at the Royal Society of Medicine, he received the rare honour of admission to that exclusive body the American Laryngo-

experience, for he counted all the leading Continental laryngologists among his friends and his friendly generous character attracted everyone.

There is one activity by which probably he would particularly wish to be remembered, and that is his long connexion with the Semon Lecture Board. When the lectureship was founded by Sir Felix Semon with the fund subscribed for him by his friends and colleagues, it was placed in the care of the University of London, and the university wisely—sometimes officially and sometimes unofficially—committed it to the charge of Tilley. With such discretion did he discharge this trust that the reputation of this lectureship stands very high. He himself spoke of it once as the blue riband of laryngology, and it was due to him that it could be so described. It was characteristic of him that for many years he persistently refused to deliver the lecture himself on account of his connexion with the management, and it was not until 1934 that his scruples were finally overborne by the vehemence of some younger colleagues.

Tilley easily attracted round him in his clinic keen workers, to whom he was kind and generous, and many of these hold important positions elsewhere. Much of his work is of permanent importance, especially that on the accessory sinuses and on the prognostic significance of a fixed vocal cord, but, above all, he will always be remembered as the perfect colleague.

Sir STCLAIR THOMSON writes:

Herbert Tilley, although not one of the founders, was certainly one of the early builders of British laryngology. He was also one of the very few survivors of the period, at the end of last century, when those who devoted themselves to a special subject had first been trained in the hard apprenticeship of general practice. This was all to their own and their patients' benefit, particularly in the art and humanity of clinical medicine. It is no longer possible owing to the length of years now required for becoming acquainted with technical details of the many methods of scientific investigation. Tilley was in general practice in the neighbourhood of Swiss Cottage when he joined the staff of the small Throat and Ear Hospital in Great Portland Street, now extinct. Fortunately he already possessed the diplomas of M.B. and B.S.Lond., as well as the F.R.C.S., which qualified him not only for aspiring to the staff of larger hospitals, but fitted him for the work he was to do in the surgical field of laryngology, which was only then beginning. Before his day the pioneers of laryngology were generally, like Sir Morell Mackenzie, Semon, and de Havilland Hall, physicians. His next step was to the Throat Hospital in Golden Square, to which I had the good fortune of being elected his colleague at the same time. He resigned this appointment when chosen as the first specialist of otolaryngology in his old school, University College Hospital, a department of which he may be regarded as the founder, where he had a long and distinguished career in a school he served loyally.

His contributions to investigations and literature extended over the whole field of his special subject, and, particularly in the clinical field, were all trustworthy and bore evidence of his extensive experience. Perhaps his best work was that on paranasal sinuses, in which he was a leading pioneer at a time when that area was still a *terra incognita*. He laid the foundation of it by his investigations into their anatomy, and the value of his clinical work was much increased by his honesty in publishing the disasters which were known to occur in the hands of many of us forty years ago. The value of his careful note-taking was apparent in his records of the occasional spontaneous disappearance in some cases of what appeared to be established sinus suppuration, and also in his reports of the changes sometimes seen in the after-histories of certain cases of paralysis of the recurrent laryngeal nerve. His intimate knowledge of laryngeal cancer, dating from the early days of laryngofissure, led him to favour the idea that there might be a constitutional tendency to cancer. The occasional reappearance of this disease, not in exactly the same area, and sometimes after a free interval of five or even ten years, was more certainly regarded by him as suggesting evidence of a local predisposition to recrudescence (as apart from recurrence) in the larynx and pharynx. Tilley's writings were clear and readable, and his contributions in debate showed clear thinking and lucid explanation, and were made more welcome by his distinct articulation and diction.

This wide and thorough knowledge of his work, with an attractive personality and a sympathetic nature, secured for him a large and enduring practice. The trust he inspired was also shown by the frequency with which colleagues consulted him when they themselves required advice in his department of practice. I have myself grateful recollection of his sympathy when seriously ill nearly forty years ago. Tilley was blessed with a devoted wife, who shared in his tastes and his sports. To both of them it was a regret that they had no children to join in their happy companionship. For both of them age, as too often happens, brought its clouds. The chronic illness of his wife was a grief to him. His own health had been threatened for some years, and the difficulties of wartime and the devotion and care for his beloved companion made the strain too great for his diminished resistance. Tilley will be sadly missed by his fellow workers: he was a friend to all of them.

E. D'ARCY McCREA, F.R.C.S., and EDITH F. W. McCREA, F.R.C.S.I.

We deeply regret to record the tragic deaths through enemy action of Mr. E. D'Arcy McCrea and of his wife, Dr. Edith F. W. McCrea. They were killed and their two children with them during an air attack on Manchester.

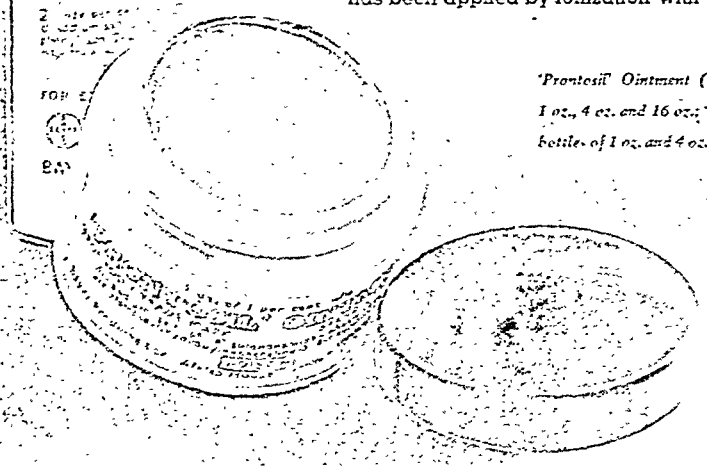
Mr. D'Arcy McCrea qualified M.B., B.Ch., B.A.O., Dublin, in 1917; three years later he took his M.D., and in 1922 the M.Ch. and the F.R.C.S.I. In 1926 he took the F.R.C.S.Eng. While still in Dublin he was assistant surgeon to Sir Patrick Dun's Hospital. At the time of his death he was honorary consulting surgeon, Eccles and Patricroft Hospital, Manchester, and honorary surgeon to Salford Royal Hospital.

We are indebted to Mr. J. B. Macalpine for the following account of his life and work.

D'Arcy McCrea qualified in Dublin in 1917 after a brilliant student career in which his name appeared many times in the prize lists. In due course he was appointed to the staff of Sir Patrick Dun's Hospital as an assistant surgeon. Almost immediately, however, the political atmosphere of South Ireland became unfavourable to one who was not of the Roman Catholic faith, and McCrea determined to seek his fortunes elsewhere. It was then that he joined me as registrar in the urological department of the Salford Royal Hospital. From about 1922 to the present time I have enjoyed an association and collaboration which continued quite unclouded by any misunderstanding until rudely broken by this tragedy. In due course McCrea gained a place on the assistant surgical staff of the Salford Royal Hospital, and for the last few years had been on the full staff. As a lieutenant he was a most loyal and willing helpmeet, careful, painstaking, and reliable in his routine work, and always willing and anxious to take up a new problem and capable of following it intelligently and studiously. In his earlier days he did much admirable work on the musculature of the bladder, especially of the bladder neck, subjects of which the difficulties are well known. He applied himself also to many questions concerned with the physiology of that organ, working out some of them in the physiological department of the Manchester Medical School, and also making contributions to the literature on the indications for presacral neurectomy in disturbances of bladder function. For the last ten years McCrea's principal interests

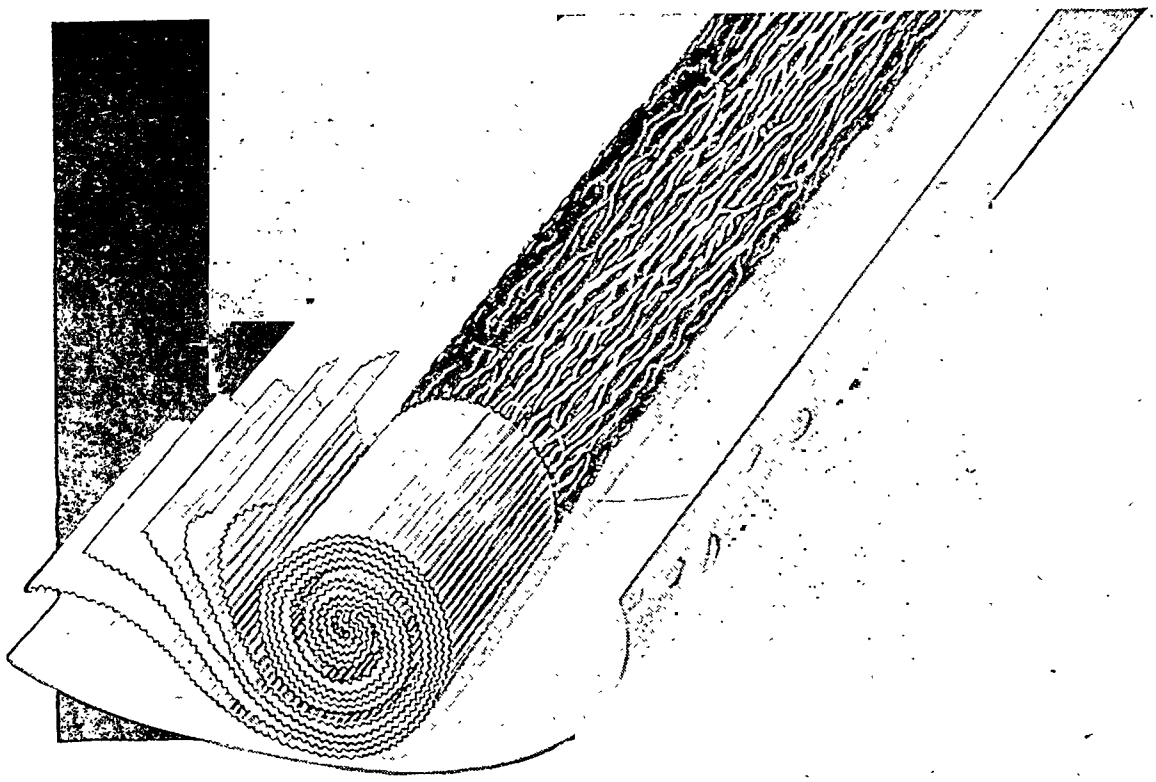
local CHEMOTHERAPY

'PRONTOSIL'



TRADE MARK BRAND OF PREPARATION

OINTMENT & SOLUTION



CHRONIC resistant lesions such as varicose ulcers, infected wounds and burns respond poorly to oral and parenteral chemotherapy. In these cases a stimulating, deodorant and anti-bacterial action is produced by the application of 'Prontosil' Ointment or Solution, the choice of agent depending upon the nature of the lesion. 'Prontosil' Solution is also of value in ophthalmic infections, and, experimentally, it has been applied by ionization with encouraging results.

'Prontosil' Ointment (1%) is available in jars of 1 oz., 4 oz. and 16 oz.; 'Prontosil' Solution (2½%) in bottles of 1 oz. and 4 oz.

A five-fold protection against throat irritants

The five protective layers of the du Maurier filter tip — pure white vegetable tissue interleaved with cellulose fibre — form a filter through which no straight stream of smoke is allowed to impinge on the tongue. Partly selective in its action, the tip retains those pyridine bases and non-volatile bodies generally regarded as the primary cause of throat irritation. No shreds of tobacco can pass the lips. The result is a cool, clean cigarette that can be smoked without inconvenience even by those with sensitive throats.

du MAURIER

the perfect cigarette with the exclusive filter tip

CORK TIP IN THE RED BOX — du M — PLAIN TIP IN THE BLUE BOX

were in diseases of the male genital tract, a subject on which he had accumulated a big fund of knowledge and an exceptionally large clinical experience. It was his intention to produce a series of monographs on this branch of surgery, and the book on diseases of the urethra and penis published so recently as May, 1940, was but the first of these. The work on other sections was well advanced, and I know that a great amount of unusually rich material, particularly that referring to disease of the testicle, has most unfortunately been lost, together with pathological specimens collected over many years and numerous drawings of their macroscopical and microscopical features. The book mentioned has been more than well received, but I know that subsequent sections would not have fallen behind the standard already set. So much valuable material lost is lamentable, but its loss pales beside that of the life thus wantonly and cruelly destroyed—a life which showed much accomplished, yet more waiting to be garnered.

McCrea was not a club man nor one who went out much in society. Few knew him intimately. Rather reserved and possibly shy, his interests were in his home and his family, and he was a voracious reader. Yet he enjoyed good conversation and meeting men of similar interests, as, for instance, at the dinner of a scientific society. Twenty years ago he became the first string in the Irish lawn tennis team, and on coming to Manchester was a regular member of the Lancashire team. He was a formidable singles player, and when representing Ireland in the Davis Cup it was his lot to face the redoubtable Tilden. However, he took a handful of games from his opponent, and the latter is credited with the remark that "had McCrea not been so keen on surgery he might have become a world beater."

Dr. Edith F. W. McCrea qualified B.A., M.B., B.Ch., B.A.O., Dublin, in 1921. She took her D.P.H. in 1922 and in 1925 the F.R.C.S.I. She was honorary surgeon to the Manchester Babies' Hospital, surgical registrar and surgical assistant, Ancoats Hospital, and surgical assistant, Stretford Hospital, Manchester. A colleague writes:

Edith McCrea was clear-cut, physically and mentally, and her heredity, training, and environment were sharply etched in her personality. The daughter of an able Anglo-Irish family, her father an Indian Civil Servant and her aunt, Miss Sophie Bryant, one of England's best-known educationists, she was trained at Cheltenham College and Trinity College, Dublin. Coming to Manchester after a career distinguished both academically and in the field of sport, she became resident medical officer at the Manchester Babies' Hospital. Intent on surgery, she took the F.R.C.S. Ireland, and later was appointed honorary surgeon at the same hospital. She also worked at Ancoats Hospital and the Stretford Memorial Hospital. She was a quick and accurate worker and a precise writer. We know that she was about to publish a paper on pyloric stenosis, the outcome of many years of careful preparation, but we fear this may have been lost in the raid. Intolerant of those she considered fools, she had a smile and charm that won her way, and with children she was delightful. She was the devoted mother of two children, who were already showing that they had inherited their parents' ability.

ANDREW TRIMBLE, M.B., B.CH.

The death of Dr. Andrew Trimble, former Chief Tuberculosis Officer for Belfast, removes a prominent and popular member of the medical profession in Ireland.

Andrew Trimble, who was born at Dungannon in 1867, graduated M.B., B.Ch., B.A.O. at the old Queen's College, Royal University of Ireland, in 1895, and was in general practice for several years. He took his D.P.H.Belf. in 1910. He had the distinction of being the first Chief Tuberculosis Officer for the city of Belfast, a position which he filled with ability for upwards of a quarter of a century. During this time he saw the death rate from consumption fall from 209 to 78 per 100,000. While still a young man he was elected to the council of the county borough of Belfast, and in this capacity took a keen interest in the activities of the public health department and in the local administration of the Children's Act. His main interests in life were the education of the public in health matters and the welfare and health of children, for whose benefit he established in Belfast an open-air day school, the first of its kind in Ireland. In 1925 Dr. Trimble made a special journey to Switzerland to investigate Spahlinger's work. He also visited Prof. Moelgaard at his laboratory in Copenhagen, and there obtained the first supplies of sanocrysin for experimental use in Belfast. In 1928 he was one of those chosen by the Joint Tuberculosis Council to visit Canada to report upon the progress of the research work there. He also went to the United States on two occasions to learn the latest developments in the diagnosis and treatment of this disease.

Dr. Trimble was a man of diverse interests and catholic tastes. It would be difficult to find a medical man who got through more intensive medical reading, yet he took a keen delight in the literature of history, biography, and archaeology. He toured Europe, and visited the ruins of Troy, ancient Babylon, the Pyramids, and Palestine. He was associated with a large number of social and philanthropic bodies, and was noted for his generosity and charity to the many services and works in which he was interested. He was a member of a number of medical societies, and had held high office in some of them. When the British Medical Association met at Belfast in 1937 he was vice-president of the Section of Tuberculosis. He was well known at tuberculosis conferences, where his views were always heard with interest and respect. A prominent medical officer of health said of him: "I have known him for almost thirty years, and from the first time I met him I regarded him as a man of unparalleled gifts: I have never changed that opinion." He was much loved, and will be greatly missed by his former colleagues and staff at the tuberculosis institutes.

EDGAR OLIVE TURNER, M.B.

We regret to record the death of Dr. Edgar O. Turner of Great Missenden at the age of 74. Dr. Turner was educated at University College in the old Gower Street days, and from there he went to University College Hospital for his medical training, working under Sir Thomas Barlow. He qualified M.R.C.S., L.R.C.P. in 1888, and in the following year M.B. with honours. In 1894 he started practice in Great Missenden and soon became a great favourite in the district, remaining in actual practice there for nearly fifty years. His chief endeavour seemed to be to lighten the burden of those with whom he came into contact: he was regarded by his patients as their friend and confidant as well as their doctor. Turner was deeply inspired by the Christian faith and was a churchwarden for many years. His local activities included that of Justice of the Peace for Bucks and chairman of the Parish Council for over forty years. There was no more loyal member of the B.M.A., to which he had belonged for forty years, he was president of the South Midland Branch in 1922–3, a representative in the Representative Body from 1926 to 1932, a member of the Central Ethical Committee and its Standing Subcommittee from 1919 to 1921, and a member of the Central Council from 1918 to 1924. He was also a representative on the Bucks Insurance Committee. By nature kind and sympathetic, he will be sadly missed by all who knew him.

We regret to record the death on November 18, 1940, of Dr. HENRY LATHAM of Worthing at the age of 70. Dr. Latham was educated at the University of Edinburgh, where he graduated M.B., C.M. in 1892. After short periods at Malvern, Stockport (where he was visiting surgeon to the local infirmary), Hassocks, and Fleetwood he settled in practice at Peterborough in 1899 and remained there until 1924, during which time he was honorary physician and senior anaesthetist to Peterborough Infirmary, and medical officer and public vaccinator for the Peterborough district of the Peterborough Union. In 1935 he moved to Worthing. He had been a member of the British Medical Association for thirty years.

We regret to record the death at Devonport on December 4, 1940, of Dr. GEORGE FREDERIC GLINN at the age of 75. Dr. Glinn received his medical education at St. Mary's Hospital, and qualified M.R.C.S., L.R.C.P. in 1889. After a short period at Devonport he went to live at Bicester, where he practised for some seven years. In 1900 he settled in practice at Camden Square, London, where he remained until last year. He had been a member of the British Medical Association for thirty-nine years, and was chairman of the old St. Pancras and Islington Division in 1910.

We regret to announce the death on December 12, 1940, at the age of 67, of Dr. EDWIN GARRETT BUNBURY. Educated at Wellington College, Bunbury then went to Cambridge University, completing his medical education at Bristol; he qualified M.R.C.S., L.R.C.P. in 1898. After holding the appointment of resident medical officer at Clifton Dispensary he was in practice for some years at the Lizard and Mullion, Cornwall. He saw service in the last war for two years in France as a captain in a field ambulance, at No. 30 General Hospital, Calais, and at another base hospital at Etaples. He then practised for four years at Colsterworth, Lincolnshire, before going to Thorverton, Devon, where he was in practice for fourteen years until he retired to Ottery St. Mary in 1939. A wide circle of Dr. Bunbury's former patients in the rural district of Thorverton will mourn the death of one who had long been a welcome visitor as general adviser and friend as well as doctor, for though of a modest and retiring disposition he obviously loved the country folk, and was for many years chairman of the British Legion at Thorverton. He was a member of the British Medical Association for thirty-five years, and was a most regular attender at all its local meetings and those of the Devon and Exeter Medico-Chirurgical Society. He leaves a widow, a daughter, and a son now in the R.A.F.

DR WILLIAM SAVILL HENDERSON, who died at Parkstone on December 17, 1940, was the son of the late Mr. Gavin Henderson of Liverpool. He qualified M.B., Ch.B. of the Victoria University of Manchester in 1899, and in the same year took his M.R.C.S., L.R.C.P. In 1906 he obtained the M.D. of the University of Liverpool. His resident posts included those of house-surgeon and house-physician at Liverpool Royal Infirmary, he was also assistant demonstrator of physiology and anatomy at the Liverpool School of Medicine, and a Gee Fellow in anatomy at the school in 1900–1. He was in practice in Liverpool until 1919. In the following year he became medical officer of health to the Helston Rural District and medical officer and public vaccinator for the fourth Helston district. In 1923 he moved to Taunton and in 1926 was appointed medical officer to Sedbergh School, a post he held until 1928, when he moved to Paddock Wood, Kent. He went to Manchester in 1935. He had been a member of the British Medical Association for thirty-six years.

DR. ROBERT GEE STERLING, who died suddenly after a long illness on January 3 at his home at Ash Vale, near Aldershot, was the son of the late Canon Robert Sterling, M.B., B.S.Durh., founder of the Church Missionary Society's Hospital in Gaza, Palestine. Dr. Sterling qualified M.R.C.S., L.R.C.P. from the London Hospital in 1915, and served as a captain in the R.A.M.C. from 1916 until the end of the war, principally in Palestine. At the close of hostilities he, with his young wife and family, returned to Gaza and rebuilt the mission hospital, which had been bombed by the British during the occupation of the town by the Turks, who were using the premises as an ammunition store. The hospital was renamed the Sterling Memorial Hospital in memory of Dr. Sterling's father. Dr. Sterling remained as medical superintendent of the hospital in charge of the 150 beds until a serious illness overtook his wife and he was obliged to return to England. For the past ten years he has been in practice at Ash Vale, where his straightforwardness, devotion to his work, and untiring efforts endeared him to a wide circle of friends, colleagues, and patients. He was a staunch supporter of the British Medical Association, which he joined in 1929, and was a member of the executive committee of the Guildford Division from 1935 to 1938, and vice-chairman of the Division 1938–9. Dr. Sterling is survived by his wife, the daughter of the late Rev. Greenway of Eldon, Co. Durham; they had three sons and three daughters.

DR. JOHN STRATFORD HALL, who died recently at Sheffield at the age of 70, was the son of Anthony Hall of Binchester Hall, Bishop Auckland, and came of an old seafaring family. He qualified M.B., B.S.Durh. in 1892, subsequently taking the B.Hy. in 1897. He began practice in the Manchester area, but in 1907 he went to the Hillsborough district of Sheffield. In 1914 he joined up, and the following year went to France, where he was rather badly gassed. He then became sanitary officer of camps at Belton Park and Harrowby. After the war he returned to general practice. His patients were to be found in both town and country, but his heart was obviously in the country part of his practice. As might be guessed from his heredity he possessed individuality and personality; his kindly, cheery manner was a great help to his patients, in whose service he never spared himself. To the last he was keenly interested in the progress of medicine and surgery. He was a great reader and always carried some books about with him in his car, so that he could, if he had half an hour to spare, draw the car up in some corner of the moors or valleys which he loved and sit down and read. He was one of the best-read medical men in the district. During the last few months, in spite of ill-health due to a failing heart, he not only carried on his practice but was able to attend medical boards; he enjoyed the opportunity which this work gave him of meeting his colleagues. He was also in charge of a first-aid post. For many years he was doctor to the Cripples' Home at Loxley. He had been a member of the British Medical Association since 1908. His loss will be regretted by many patients and colleagues.

DR. PATRICK JOHN CARROLL, who died on January 4, was educated at Queen's College, Cork, where he was a senior scholar, and graduated M.B., B.Ch., B.A.O. of the Royal University of Ireland in 1902. During the war of 1914–18 he served in the R.A.M.C. as a lieutenant. He had been in practice in Manchester since 1909, where he was a well-known and popular member of the profession. He joined the British Medical Association in 1926.

A neurophysiological section has recently been added to the Carolinian Medical Institute in Stockholm, Sweden's principal medical school. It is under the direction of the Finnish-Swedish scientist Prof. Ragnar Granit, a pioneer in and an international authority on electrophysiology. Prof. Granit has taken with him from Helsingfors electrical and optical precision instruments, partly acquired or designed with means contributed by the Rockefeller Foundation. The rooms in which the new section is housed have been specially prepared so that when weak "action currents" in the cells investigated have to be amplified there shall be no interference from outside. Included in the equipment of the new section are two spectrophotometers and their amplifiers and several cathode-ray oscillographs.

EPIDEMIOLOGICAL NOTES

Infectious Diseases for the Week

The incidence of measles and whooping-cough increased during the week, the present levels being the highest so far recorded in 1940. Although the incidence of diphtheria has fallen slightly, as in the previous week, the severity of the disease is causing anxiety. A high incidence of non-fatal cases of diphtheria might prove an advantage in the long run, as the mass immunity would thereby rise rapidly. A safer, cheaper, and less unpleasant way to achieve immunity, whether in the individual or in the herd, is to inoculate non-immunes with one or other of the antigens now available. The possible effect of evacuation on the incidence of diphtheria may be considered from notifications for the corresponding weeks of 1940, 1939, and 1938 for the largest towns: Birmingham 32, 11, 20; Liverpool 73, 32, 57; London 46, 25, 173; Manchester 18, 10, 29; Edinburgh 34, 9, 13; Glasgow 146, 45, 81; Belfast 22, 16, 11. Although the incidence in London and Manchester is higher at present than in the previous year it is much lower than in the last "normal" year, 1938. On the other hand, in the other large towns the incidence at present is much higher in some instances approximately three times higher than in 1938, while the percentage of cases proving fatal is even greater. The figures for the various administrative districts suggest that the high incidence in the country as a whole is due to spread in the densely populated areas (from which an appreciable proportion of the presumed non-immunes have been evacuated), and not, as might have been expected, to the appearance of diphtheria in epidemic form in the reception areas, despite reports of such outbreaks in some quarters. During the week under review the counties more heavily infected were: Lancaster 235 (Liverpool 73, Manchester 18, Bootle 14, Fleetwood M.B. 10, Huyton with Roby U.D. 10); Glamorgan 125 (Swansea 39, Merthyr Tydfil 15, Cardiff 11), Devon 92 (Plymouth 58, Brixham U.D. 6, Newton Abbot R.D. 4, Exeter 4); Yorks, North Riding, 79 (Middlesbrough 68); Durham 78 (Jarrow M.B. 15, Sunderland 13, Gateshead 10, Stockton-on-Tees M.B. 9); Gloucester 54 (Bristol and Gloucester 23 each); London 46; Chester 44 (Birkenhead 12, Stockport 9); Leicester 44, of which 29 were in the city.

Quarterly Returns Ended September 30, 1940

Eire.—During the quarter 14,358 births were registered, of which 7,318 were males and 7,040 females, corresponding to a rate of 19.4 per 1,000 of the estimated population. Illegitimate births represented 3.1% of the total births. Deaths numbered 8,530 (4,400 males, 4,130 females), equivalent to an annual rate of 11.5 per 1,000 and 0.2 below the third quarter of the previous year. The infant mortality rate was 50 per 1,000 births registered, compared with 52 in the previous year. The principal infectious diseases accounted for an annual death rate of 0.4 per 1,000; the mortality from typhoid fever, measles, scarlet fever, and diphtheria fell, but rose for whooping-cough and diarrhoeal diseases in children under 2 years. Deaths from puerperal causes were represented by a rate of 2.9 per 1,000 births registered (0.4 for puerperal infection and 2.5 for other puerperal causes), being 0.2 lower than in the third quarter of the previous year.

Northern Ireland.—There were 6,334 births (3,254 males, 3,080 females) during the quarter, equivalent to an annual rate of 19.5 per 1,000 estimated population, and 0.1 below that for the third quarter of 1939, and 0.6 below the average for the third quarters of the five years 1935–9. Illegitimate births formed 4.5% of the total births registered. Deaths numbered 3,759 (1,921 males and 1,838 females), corresponding to an annual rate of 11.6, and 0.2 above the rate for the corresponding quarter of 1939. Infant mortality for the quarter was 76 per 1,000 births, compared with 55 for 1939 and an average of 61 for the preceding five years. The principal infectious diseases accounted for 0.76 of the total death rate recorded, compared with 0.51 in the corresponding quarter of 1939. Increases in deaths were recorded from diphtheria, scarlet fever, whooping-cough, measles, enteric fever, and diarrhoeal diseases in children under 2 years of age, but deaths from influenza were nearly halved.

No. 50 for 1940

INFECTIOUS DISEASES AND VITAL STATISTICS

We print below a summary of Infectious Diseases and Vital Statistics in the British Isles during the week ended December 14, 1940.

Figures of Principal Notifiable Diseases for the week and those for the corresponding week last year, for (a) England and Wales (London included), (b) London (administrative county), (c) Scotland, (d) Eire, (e) Northern Ireland.

Figures of Birth and Deaths, and of Deaths recorded under each infectious disease, are for (a) The 126 great towns in England and Wales (including London), (b) London (administrative county), (c) The 16 principal towns in Scotland, (d) The 13 principal towns in Eire, (e) The 10 principal towns in Northern Ireland.

A dash — denotes no cases; a blank space denotes disease not notifiable or no return available.

Disease	1940 (a)	1940 (b)	1940 (c)	1940 (d)	1940 (e)	1939 (Corresponding Week) (a)	1939 (b)	1939 (c)	1939 (d)	1939 (e)

* 1 case mixed infection diphtheria and scarlet fever.

† Notification in certain administrative areas only.

‡ Includes primary form in figures for England and Wales, London (administrative county), and Northern Ireland.

§ Since January 1, 1940, figures for London (b) have been for deaths from all forms of pneumonia; the corresponding figures for 1939 relate to deaths from lobar pneumonia only.

Medical News

A meeting of the Shaftesbury Military Hospital Medical Society will be held at the hospital on Tuesday, January 21, at 3 p.m., when Major-General Priest will give an address on "Cerebrospinal Meningitis."

Mrs. Neville-Rolfe, Secretary-General of the British Social Hygiene Council, has been awarded the Snow Medal for 1941 by the American Social Hygiene Association. This medal is given for "distinguished service to humanity," and is named after Dr. Snow, the first Director of the American Association, which was formed in 1913. Mrs. Neville-Rolfe is the fourth recipient of the medal and the first woman to be so honoured.

There are shortly to be shipped to this country the entire equipment of the hospital and laboratories and the complete medical and nursing staffs of the American Red Cross Harvard Hospital for Infectious Diseases. Harvard is providing the medical staff, the laboratory equipment, and $100,000 a year towards the financing of the venture, while the American Red Cross is giving a sum of $300,000, as well as the hospital itself, its equipment, and the nursing staff. Dr. John E. Gordon, Professor of Preventive Medicine and Epidemiology at Harvard University and Director of the Hospital, has already arrived in this country from Lisbon.

Two further instances of American generosity have come to our notice this week. The American Red Cross have bought for this country sufficient material for the preventive inoculation of 1,000,000 children against diphtheria. This was done in response to an appeal from the Ministry of Health through the British Red Cross, and part of the consignment is being hurried here by Clipper. The remainder is to follow by sea. The third instance concerns a tablet containing vitamins A, B, C, and D, flavoured with sugar and cinnamon, which is being manufactured under the direction of six New York physicians. The British-American Ambulance Corps is raising funds to send to England 9,000,000 of these tablets this year, sufficient for 4,000 children to take six tablets each daily. The first consignment has already left New York.

To avoid overlapping, states the *Times*, and to ensure that the sending of medical and surgical supplies, doctors, and nurses from the United States to this country will be regulated according to need, the British Government has decided that all requests made on its behalf shall be directed through the British Red Cross Society solely to the American Red Cross. Any offers of assistance of this kind received by the Government from American organizations will be referred in the same way.

The Royal Society of Medicine (1, Wimpole Street, W.1) intends to publish in the December number of the *Proceedings* the two discussions which were held recently at the Society's house, one by the Section of Medicine on "Traumatic Haemothorax" and one by the Section of Surgery on "Chest Injuries." The two discussions will be issued as a combined reprint at 2s. per copy. As the number is limited early application is advisable.

The exemption from key industry duty of all articles at present exempt, except dial, chinoline, dinitro-orthocresol, ethyl orthoformate, and metaldehyde, has been renewed until June 30, 1941.

At the suggestion of the Minister of Health, Lord Horder, accompanied by one of the Ministry officials, has visited a number of provincial centres at Bristol, Manchester, and Liverpool in order to assist the regional and local authorities on shelter matters.

Prof. A. Einstein, who has been professor of theoretical physics in the Institute for Advanced Studies at Princeton since 1933, has been admitted to American citizenship.

Prof Angel H Roffo has been appointed incumbent of the new chair of "cancerology" established at the faculty of medicine of the University of Buenos Aires.

Letters, Notes, and Answers

All communications in regard to editorial business should be addressed to THE EDITOR, BRITISH MEDICAL JOURNAL, B.M.A. HOUSE, TAVISTOCK SQUARE, W.C.1.

Authors desiring REPRINTS of their articles must communicate with the Secretary, B.M.A. House, Tavistock Square, W.C.1, on receipt of proofs. Authors over-seas should indicate on MSS. if reprints are required, as proofs are not sent abroad.

ADVERTISEMENTS should be addressed to the Advertisement Manager (hours 9 a.m. to 5 p.m.). Orders for copies of the *Journal* and subscriptions should be addressed to the Secretary.

TELEPHONE NO.—B.M.A. and *B.M.J.*: EUSTON 2111.

TELEGRAPHIC ADDRESSES.—EDITOR, *Aitiology Westcent, London;* SECRETARY, *Medisecra Westcent, London.*

B.M.A. SCOTTISH OFFICE: 7, Drumsheugh Gardens, Edinburgh.

QUERIES AND ANSWERS

Income Tax

Allowance of Subscriptions

"G. L. H." inquires if the refusal to admit a claim for deduction of B.M.A. subscriptions is correct.

*** Such subscriptions are allowable if the earnings are assessable under Schedule D—i.e., as the profits of independent professional work—but if they are assessable under Schedule E, as the profits of "employment," they are allowable only if membership of the Association is a condition of the employment. As a result of this rule they would apparently be inadmissible in the case of employment under the Crown.

House in Hands of Caretaker

"B. J." maintained a house which was in charge of a non-resident caretaker. He placed a board in the garden stating that he was away doing special work but that messages put through the letter-box would be forwarded. Can he claim a deduction for the rent, telephone, etc., of that house?

*** We fear not. The amount of professional use to which the premises were put in such circumstances hardly justifies the claim that they were occupied professionally.

Assessment of Partnership

"A" and "B" have been in partnership for many years; and have been assessed separately for their net shares of the profits. This year a single assessment has been made on the firm, and when one partner sent a cheque for his share of the tax the collector returned it saying it could be accepted only on the understanding that if the other partner defaulted he would be responsible for the whole amount.

*** The profits of a partnership are assessed by law in one sum on the firm, and the old practice of assessing the partners separately was legally incorrect. The collector's action, however, seems unnecessarily irritating in the circumstances. In theory the junior partner should pay his cheque into the firm's account or to the senior partner, and the latter should discharge the firm's liability.

Treatment of Gastric Flatulence

"B. A. J." writes: I should be grateful for any suggestions as to treatment or diet in the case of a woman aged 47 who suffers from gastric borborygmi. These "rumblings" occur at all times of the day, both before and after meals, and cause her some embarrassment and mental distress. Otherwise she is quite a normal healthy woman and has no other gastric symptoms. Ordinary routine treatment for flatulence by alkaline powders, charcoal, etc., has so far made no difference to the condition.

Dysmenorrhoea

Dr. A. A. LOESER (London, W.1) writes: In reply to "Country Practitioner" (December 28, p. 924), as the patient has to work I would recommend very strongly a subcutaneous implantation of 25 mg. of oestrone or oestradiol. This implantation takes only a minute to perform, and can be done in the doctor's own surgery.

LETTERS, NOTES, ETC.

Diphtheria Incidence

Dr. R. M. COURTAULD (Earls Colne, Essex) writes: Will an immunologist or a statistician kindly explain how it comes about that, in spite of all the Schick-testing and immunizing that have been done, the diphtheria incidence, as shown by the figures given week by week under "Infectious Diseases and Vital Statistics," is considerably higher than it was at the corresponding time last year?

SUPPLEMENT TO THE
BRITISH MEDICAL JOURNAL
LONDON SATURDAY JANUARY 18 1940

THE PROTECTION OF PRACTICES SCHEME IN OPERATION

Now that schemes for the protection of practices of doctors who are absent on Service have been in operation for a full year it is considered that the following account, which has been sent to us from Gateshead, an area in which there has been no large influx or evacuation of the population, may be of interest.

The Gateshead Divisional area consists of two parts for the purpose of the scheme, defined by the boundary between the Gateshead Borough and Durham County Insurance areas. The former area comprises mixed practices equally made up of private, National Health Insurance and Public Medical Service patients. The latter area consists entirely of colliery practices with large cohort lists. The actual administration for the county area has been in the hands of the clerk to the County Insurance Committee, who directs the County Bureau, which controls the scheme in the rural areas of the whole county. In the Gateshead Borough area the administration is in the hands of two subcommittees of the Emergency Committee, one the Insurance Bureau, consisting of the chairman, vice-chairman and secretary of the Emergency Committee and the clerk to the Insurance Committee, and the other the Private and P.M.S. Bureau, consisting of the above members of the Emergency Committee and the secretary of the Gateshead Public Medical Service.

The actual scheme follows very closely the British Medical Association's Model Scheme, and of sixty-two doctors practising in the area sixty-one have signed the necessary agreement. The practitioner who is a non-signatory is in an outlying practice in the county area. Of thirteen doctors practising in the county area three are on Service. The deputy system has been adopted, and as the absent practitioners are in all cases partners no actual pooling of practices has been necessary. Payment for N.H.I. transfers from practices where a partner is an absentee has been made at the rate of half the ordinary N.H.I. capitation fee to acting and absentee practitioners. Expenses have been a primary charge of 5% on all moneys handled by the Bureau—for example, the N.H.I. cheques payable to a partnership on behalf of the absentee partner. Because of the nature of the practices the actual adjustment of moneys between the acting and absentee practitioners has been very small.

In the Gateshead Borough area seven principals are absentees; three practices have been pooled; three partners are absentees; and one principal who is an absentee has carried on his practice with an assistant deputizing. In the case of N.H.I. and P.M.S. patients the practice pool system has been adopted—that is, the capitation fee payable to an acting practitioner varies with the practice from which the patient comes. Payments in respect of patients who contract out of a partnership or deputy practice are made on a basis arrived at by averaging the pool values. In the case of private and P.M.S. patients a drug fund is formed for acting practitioners based on a 5% credit to the acting from the absentee practitioner.

During the first quarter of the scheme's operation the expense deduction was 7½%; for the last three quarters this figure has been reduced to 5% over all classes of practice. Since the N.H.I. Bureau costs much less to run than the Private Bureau a cash transfer is made quarterly from the former to the latter. The result of the above deduction is that in the case of insured patients acting practitioners divide 45% of an absentee's cheque while the absentee gets 50%. A partnership or a "deputy" practice receives 97½% of its cheque on behalf of the absentee. The apparent deduction of 2½% only is due, of course, to the fact that the N.H.I. Bureau handles only one-half of the full absentee's cheques, the absentee being paid his 50% direct by the Insurance Committee. In the case of private and P.M.S. patients the whole of the income is handled by the Bureau; in consequence 52½% of the income is paid to acting practitioners and 42½% to absentee practitioners. In actual figures the results were as follows:

Insured Patients

Total number of patients on single-handed absentees' lists: January 1, 1940, 2,691; July 1, 1940, 2,531.

Total number of patients on partnership and nominee practitioners' list: January 1, 1940, 4,886; July 1, 1940, 4,701.

Total number of patients of absentee practitioners on temporary lists of acting practitioners: January 1, 1940, 696; July 1, 1940, 1,391.

Total remuneration of absentee practitioners:	£	s.	d.
Single-handed practitioners	614	10	1
Partners and nominees	1,805	18	0
Total net payments to acting practitioners	576	19	7

The average quarterly unit value per temporary transfer paid to acting practitioners was 5s. 11d. for the quarter ending December 31, and fell to 2s. 4d. for the quarter ending September 30. The highest value paid in respect of any practice for any quarter was 7s. 3d. The average unit value for the whole period in respect of partnership and pooled practices was 2s. 5d. This figure will of course, in time, as more of the absentees' patients become temporary transfers, approach half the normal capitation value payable in respect of patients on a permanent list.

The total income accruing to the N.H.I. Bureau to meet expenses was £104 14s. 1d., of which £70 was transferred to the Private and P.M.S. Bureau. The expenditure of the N.H.I. Bureau was £32 10s. 6d.

The following results were obtained by the Private Bureau:

	£	s.	d.
Gross private accounts paid for year	484	13	4
Gross P.M.S. accounts paid for year, including partnerships	1,233	16	8
Total administration costs	172	17	6
Less received from N.H.I. Bureau towards such costs	70	0	0
Paid to acting practitioners (private accounts).. ..	246	7	0
Paid to acting practitioners (P.M.S. accounts).. ..	114	12	6
Paid to absentee practitioners (private accounts) ..	204	17	4
Paid to absentee practitioners, single-handed (P.M.S. accounts)	89	0	10
Paid to absentee practitioners, partners and nominated partners (P.M.S. accounts)	916	11	11

Total private accounts outstanding, £214 17s. 6d. at September 30 (Of this total £93 11s. has since been paid.)

The total of the private fees paid on account of absent practitioners is probably about one-third of that which these practices would bring in in normal times; this, I believe, has been a general finding throughout the country. The question of possible leakages has been carefully checked, and a deduction was made from the cheque of one practitioner for a misinterpretation of the scheme.

The committee now feels fairly confident that the scheme is being conscientiously administered by the acting practitioners. The discrepancy may be in part explained by the loss to absentees of new patients—there is a fair amount of movement of patients of the private class from one residential part of the Tyneside area to another—and to a tendency to "minimal" rather than "maximal" attendance, especially in the case of chronic patients of absentees. There are also a great many minor complaints which will take a patient to a doctor he knows well, but which he will put up with rather than consult a new one. In order to tighten things up still further the medical officer of health for the borough drew attention to several sources of income coming under the aegis of his department—for example, notification fees and fees payable under the Midwives Act, etc. He arranged that payment of such fees in the case of patients of absentee

practitioners would be adjusted by his department, which would pay 50% of the fee to the acting practitioner and 50% to the Bureau for payment to the absentee without deduction. Practitioners were circularized with respect to these fees and fees for insurance examinations, vaccinations, etc.

Apart from the rather unsatisfactory return from private practice, the Scheme has operated very smoothly.

Medical Services of H.M. Forces Appointments

ROYAL NAVY

Surgeon Commanders A. C. Shaw and R. A. Brown to be Surgeon Captains.
Surgeon Lieut.-Commanders J. M. McNamara and M. J. Brosnan to be Surgeon Commanders.

ROYAL NAVAL VOLUNTEER RESERVE

Surgeon Lieut.-Commander W. F. Lascelles to be Surgeon Commander.
To be Surgeon Lieutenants: H. E. Rutherford and D. M. Sheppard.
Probationary Surgeon Lieut. J. Benn to be Surgeon Lieutenant.
To be Temporary Surgeon Lieutenants: L. D. Osler, A. G. Cumming, H. S. A. Corfield, L. Jones, and G. A. Bell.
Probationary Temporary Surgeon Lieuts. A. B. Pollard, D. Walton, D. E. Meares, and J. L. Hill to be Temporary Surgeon Lieutenants.

ARMY

Colonel B. Biggar, half pay list, late R.A.M.C., having reached the age for retirement, has been placed on retired pay.
Major R. J. Blackham, C.B., C.M.G., C.I.E., D.S.O., retired pay, late R.A.M.C., has been restored to the rank of Colonel on re-employment in that rank.
Lieut.-Colonel A. G. Tresidder, C.I.E., I.M.S. (ret.), has reverted to the rank of Major at his own request whilst employed during the present emergency.
Colonel R. S. Townsend, M.C., I.M.S. (ret.), has reverted to the rank of Major at his own request, whilst employed during the present emergency.

ROYAL ARMY MEDICAL CORPS

Lieut.-Colonel (Temporary Colonel) J. A. L. Wilson having attained the age limit for retirement has retired and remains employed.
Lieut.-Colonel S. P. Sykes has retired and remains employed.
Major (Temporary Lieut.-Colonel) R. D. Davy, M.C., to be Lieutenant-Colonel.
Majors F. McKibbin and K. M. Nelson, M.C., to be Lieutenant-Colonels.
Captain T. D. M. Martin has relinquished his commission on account of ill-health.
J. E. Miller to be Lieutenant (on probation).

ROYAL AIR FORCE

Flight Lieut. O. M. Fraser to be Squadron Leader.
Flying Officers B. C. Curwood and R. Napier to be Flight Lieutenant.
To be Medical Officers with the relative rank of Flying Officer: Mary J. Allardice and Winifred A. Kane.

ROYAL AIR FORCE RESERVE

Flying Officer J. H. L. Newnham to be Flight Lieutenant.

AUXILIARY AIR FORCE

Flying Officer C. Roff to be Flight Lieutenant.

ROYAL AIR FORCE VOLUNTEER RESERVE

To be Squadron Leaders: A. C. P. Campbell and I. J. Davies.
To be Flight Lieutenants: S. I. Ballard, H. A. D. Small, T. A. Edwards, D. C. Farquharson, G. E. Hesketh, and F. T. Madge.
Flying Officers R. Carpenter, J. H. McElney, P. Griffiths, G. L. Gryspeerdt, A. Caplan, J. Watkins-Pitchford, D. A. P. Anderson, A. S. Lee, J. R. Conelly, T. A. James, W. Poskett, A. J. Smith, W. F. Walton, H. G. Vyse, T. V. Mendlesohn, T. A. W. Edwards, K. G. Bergin, C. R. Hamand, D. Stafford-Clark, and D. Sheehan to be Flight Lieutenants.
Pilot Officers J. L. Trent and J. G. M. McMurchy to be Flight Lieutenants.
Flight Lieut. C. O. Gange has resigned his commission.
To be Flying Officers: E. E. Bowen, D. I. Buchanan, C. W. D. Cole, N. Dugmid, N. G. Farrell, J. Fiddes, F. E. Fletcher, D. M. I. Freeman, H. O. Hughes, R. K. McElderry, A. G. Spencer, C. S. Ashwell, G. Beven, D. Canning, J. K. T. Cherry, H. H. Dickson, L. Fridjohn, H. L. Garstein, B. R. Isaacs, D. A. Lindsay, L. H. Lithman, R. L. P. Lytle, D. H. MacCormack, J. McGregor, C. D. Ross, J. R. Simpson, W. G. Smeaton, L. G. Tulloch, I. Young, G. Ashforth, D. M. R. Barry, G. D. S. Briggs, M. A. Charrett, D. E. Christie, I. L. W. Clancey, H. D. Elliott, C. H. Gibson, J. W. K. Harper, T. H. Hughes, J. H. Jacobs, D. L. Johnson, P. R. Latcham, P. St. G. Robinson, A. Skene, J. A. H. Smart, R. F. Stronge, L. L. Whytehead, C. M. Chambers, T. C. Corson, D. J. Dawson, W. R. Dyke, D. G. Evans, S. Gnessen, J. Phillips, E. Robinson, J. Rubie, and R. N. Stansfield.

ROYAL AIR FORCE VOLUNTEER RESERVE: DENTAL BRANCH

Flying Officer J. L. Trainer, L.R.C.P. & S.Ed., to be Flight Lieutenant.

REGULAR ARMY RESERVE OF OFFICERS

ROYAL ARMY MEDICAL CORPS

Colonel R. M. Dickson, O.B.E., has ceased to belong to the Reserve of Officers on account of ill-health.
Major H. E. P. Yorke, M.C., has ceased to belong to the Reserve of Officers on account of ill-health.
Captain (acting Major) E. J. Mannix to be Brevet Major, under the provisions of Article 168, Royal Warrant for Pay and Promotion, 1940.

TERRITORIAL ARMY

ROYAL ARMY MEDICAL CORPS

Captain A. L. Evans has relinquished his commission on account of ill-health and has resumed the rank of Captain.
Captain R. A. Kernohan has relinquished his commission on account of ill-health.
Captain R. J. Hyder has relinquished his commission on account of ill-health. (Substituted for the notification in the *Supplement* to the *London Gazette*, date September 13, 1940.)
War Substantive Captain M. K. Mellett has relinquished his commission on account of ill-health.
Lieut. F. J. Fowler to be Captain.

LAND FORCES: EMERGENCY COMMISSIONS

ROYAL ARMY MEDICAL CORPS

Lieut. R. M. Williams has relinquished his commission.
Lieut. L. L. Ratazzi has resigned his commission.
Lieuts. W. S. McBride and G. M. Gibb have relinquished their commissions on account of ill-health.
Dr. (Lieut.) Muriel Boycott has relinquished her appointment.
Dr. D. K. Small, Medical Officer with the relative rank of Captain, has relinquished her appointment on account of ill-health.
To be Lieutenants: J. Gaughan, A. Coyer, E. D. Forster, D. S. Johnson, A. W. F. Craig, W. R. Blore, M.C., J. J. McCall, T. L. Macdonald, M. D. Milne, D. Thomson, W. A. L. Macfadyen, G. C. Shepherd, R. W. Taylor, N. W. Rawlings, G. A. Bell, C. J. Cellan-Jones, S. L. Henderson, R. M. Maher, J. J. Reeks, L. R. Jordon, A. G. Brown, E. W. Evans, R. M. Johnson, J. A. Key, C. J. R. MacDonald, B. Phillips, J. M. Ross, J. C. Scott, W. F. Smyth, J. Watt, F. de Burgh-Whyte, J. W. Bigger, T. W. Carrick, J. C. Gillett, K. W. Leon, P. S. Wright, S. Adams, J. P. S. Dunn, F. H. McKenna, W. G. Q. Mills, P. Nathan, F. O. Potter, J. H. Rees, D. J. Campbell, J. Fielding, R. W. L. Hall, M. McAlley, J. D. Morgan, P. R. Rainford, D. F. Sheriff, J. S. Simmers, R. Farncombe, J. A. Perkins, J. R. D. Williams, T. C'sato, G. W. Hearn, R. A. Henson, J. P. Lask, J. J. Messant, P. J. G. Quinn, S. Samuels, B. Schwartz, B. W. Wood, E. A. Wood, T. C. Thorne, H. Barrowman, J. G. Bickerton, W. M. Down, K. J. Dunlop, R. Finlay, A. J. Fulthorpe, W. G. C. Gillies, P. D. Johnson, T. W. Lees, G. J. Levden, J. McGarrity, A. S. McKenzie, H. J. McPherson, D. J. Roberts, G. B. Royce, H. F. Strickland, F. J. Fish, J. O'D. Alexander, F. C. McLaren, G. B. Malone-Lee, H. I. H. Porcher, L. R. D. Smith, E. W. L. Thompson, T. G. Wilson, H. D. O'Brien, D. Loughridge, G. A. Anderson, G. W. Armour, S. Y. Baird, J. M. Ellis, S. T. G. Gray, W. Magowan, S. F. Mitchell, K. C. W. Shawcross, M. B. Watson, W. M. Winter, F. Dornan, E. F. Edson, W. Fielding, H. D. Hudd, K. K. Hussain, A. P. Massie, W. Morron, W. R. N. Sutherland, W. S. Thomson, H. Tatton, F. A. S. Austen, G. H. M. Hemsted, E. D. Pridie, O.B.E., D.S.O., J. Fleming, R. L. Lancaster, R. B. Campion, V. M. Skoufarides, B. S. Sabet.

COLONIAL MEDICAL SERVICE

J. B. Davy, M.B., D.F.M., has been appointed Senior Medical Officer, Tanganyika Territory.

DIARY OF SOCIETIES AND LECTURES

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—At Royal Society of Medicine, 1, Wimpole Street, W., *Mon.*, 3 p.m., Mr. L. E. C. Norbury, Carcinoma of the Rectum, with Special Reference to its Pathology and Treatment, based on a survey of cases at St. Mark's Hospital during the past ten years; *Wed.*, 3 p.m., Mr. Norman Capener, The Lumbo-sacral Joint: A Discussion upon Spondylolisthesis, Scoliosis, and Sciatica; *Thurs.*, 3 p.m., Mr. R. E. Smith, The Undescended Testicle.

VACANCIES

MEDICAL REFEREES UNDER THE WORKMEN'S COMPENSATION ACT, 1925, for dermatological cases arising in the County Court Districts of Accrington, Blackburn and Clitheroe, Blackpool, Chorley, Lancaster and Preston (Circuit No. 4), Liverpool, St. Helens and Widnes, Southport and Wigan (Circuit No. 6), Altrincham, Warrington, Birkenhead, Runcorn, Chester, Crewe and Nantwich, Market Drayton and Northwich (Circuit No. 7), Ashton-under-Lyne and Stalybridge, Burnley, Colne and Nelson, Todmorden, Congleton, Macclesfield, Hyde, Stockport and Rawtenstall (Circuit No. 10). Applications to the Under-Secretary of State, Home Office (Industrial Division), Cleland House, Page Street, S.W.1, by February 1.

MEDICAL REFEREES UNDER THE WORKMEN'S COMPENSATION ACT, 1925, for dermatological cases arising in the County Court Districts of Abergavenny, Pontypool and Blaenavon, Monmouth, Cardiff and Barry, Chepstow, Newport, Tredegar, Abertillery and Bargoed (Circuit No. 24), Aberdare and Mountain Ash, Merthyr Tydfil, Pontypridd, Ystradyfodwg and Porth, Bridgend, Neath and Port Talbot (Circuit No. 30), and Aberayron, Cardigan, Carmarthen, Llandilo Fawr and Ammanford, Lampeter, Llandovery, Llanelly, Newcastle-in-Emlyn, Aberystwyth, Haverfordwest, Pembroke Dock and Narberth, and Swansea (Circuit No. 31). Applications to the Under-Secretary of State (Industrial Division), Home Office, Cleland House, Page Street, S.W.1, by February 1.

APPOINTMENTS

COLLS, MARGARET, M.R.C.S., L.R.C.P., Temporary Medical Officer, Women's Internment Camp, Isle of Man.

O'FARRELL, P. T., F.R.C.P.I., D.P.H., D.T.M., Visiting Physician, St. Vincent's Hospital, Dublin.

EXAMINING FACTORY SURGEONS.—W. R. H. Pooler, M.B., B.Ch., for the Wellington District (Shropshire); D. A. Richards, M.B., Ch.B., for the Appleby District (Westmorland).

B.M.A.: Branch and Division Meetings to be Held

ABERDEEN BRANCH: CITY OF ABERDEEN DIVISION.—At Marischal College, Aberdeen, Tuesday, January 21, 8.30 p.m. Prof. E. W. H. Cruickshank: The Factors which determine the Essential Foods in Wartime.

DORSET AND WEST HANTS BRANCH: BOURNEMOUTH DIVISION.—At Boscombe, Wednesday, January 22, 3.30 p.m. Address by Mr. L. D. Gammans, Deputy Regional Information Officer, Ministry of Information: The New Method of Waging Warfare.

SOUTH WALES AND MONMOUTHSHIRE BRANCH: SWANSEA DIVISION.—At Mackworth Hotel, Swansea, Thursday, January 23, 2 p.m. B.M.A. lecture by Dr. W. Ernest Lloyd: Diseases of the Chest (illustrated).

BIRTHS, MARRIAGES, AND DEATHS

The charge for inserting announcements under this head is 10s. 6d. This amount should be forwarded with the notice, authenticated with the name and address of the sender, and should reach the Advertisement Manager not later than the first post Tuesday morning to ensure insertion in the current issue.

MARRIAGE

STEVENSON—DUKE.—On January 2, 1941, at Holy Trinity Church, Cambridge, Claude M. Stevenson, M.D.Cantab., to Johanna Duke, widow of the late W. H. Duke, Fellow of Jesus College.

DEATH

MCKAIL.—On January 10, 1941, at Abington, 81, Carmyle Avenue, Carmyle, Glasgow, Robert Buchanan Forbes McKail, M.B., Ch.B., D.P.M., late Medical Superintendent of Brockhall Certified Institution for Mental Defectives, Langho, Lancashire.

ACUTE BRONCHIOLITIS IN CHILDREN

BY

DOUGLAS HUBBLE, M.D.

Physician to the Derbyshire Hospital for Sick Children

AND

G. R. OSBORN, M.B., B.S.Melb.

Pathologist to the Derbyshire Royal Infirmary and Derbyshire Hospital for Sick Children

(WITH SPECIAL PLATE)

"Capillary bronchitis may well be termed the essential lesion of influenza" - HORDER.

Capillary bronchitis, or, as it is better called, acute bronchiolitis, is not generally admitted to be a clinical or pathological entity. The pathologists, the paediatricians, and the writers on diseases of the chest for the most part deny it a separate existence. The general view is expressed by Norris and Landis (1938): "The latter term [i.e., capillary bronchitis] should never be used. While a lesion limited to the finer bronchioles is possible theoretically, practically it never exists alone, as an inflammatory process invading the swollen bronchi inevitably extends to the anatomically related and contiguous vesicles as well. The term 'bronchopneumonia' is much the most preferable designation, and by common consent is the one now in general use." It is difficult to share this view when one has, in an influenza epidemic, seen dyspnoeic and cyanosed children die in asphyxia. Holt and McIntosh (1933), for example, express a contrary opinion when, in an account of acute bronchiolitis in children, they write: "The symptoms, however, are due chiefly to a bronchitis which extends to the smallest tubes. Fibrinous exudate, and in some cases oedema, cause obstruction with great respiratory distress." Horder (1933), too, in the admirable article on influenza quoted above, writes: "But the dominant feature, rarely absent in any really severe case, is a condition of capillary bronchitis, with intense pulmonary congestion. This may be unilateral or bilateral, is more often basal than apical, but it is not seldom universal. This condition may well be termed the essential lesion of the disease, for even when actual consolidation of the lung is present this is quite often an incident by comparison, and if the patient dies he dies with the consolidation rather than of it."

In the catarrhal epidemic of January–March, 1940, the majority of patients escaped with an acute pharyngitis, but in many the larynx, the trachea, the bronchi, the bronchioles, or the alveoli were progressively involved. When the inflammation extended to the bronchioles dyspnoea and cyanosis became urgent symptoms, and although this phase was most obvious in babies and young children it was by no means absent in adult infections. Discussion here will, however, be limited to this condition of acute bronchiolitis in children, for in them it ranks as a first-class medical emergency.

The cases on which this paper is based were seen mainly in hospital practice. Fifty children were admitted to the Derbyshire Hospital for Sick Children with an acute respiratory infection during the first ten weeks of 1940. Twenty-seven of these were under the age of 1 year. Seven children died, all of them under the age of 2. Six other children were seen in family and consulting practice, and although these added little to the clinical picture they included two deaths in healthy middle-class children, aged respectively 4 and 2, and corrected the common impression that fatalities do not occur except in infants or in debilitated children. It is not suggested that all these children were suffering from acute bronchiolitis: in some of them the final diagnosis was acute bronchitis and in others bronchopneumonia, but in many it was possible to diagnose a phase in the infection when the small bronchioles were filled with exudate. Occasionally the children died in this phase of obstructive dyspnoea; some recovered without further extension of the inflammatory process, but more often the condition went on to bronchopneumonia, in three cases with a fatal termination some weeks later. No detailed case histories will be given, but a composite clinical picture of acute bronchiolitis will be attempted, and the treatment of the condition will be discussed in detail. In order that the clinical diagnosis may be substantiated the pathological appearance of the lungs in an infant who died in asphyxia will be described and illustrated.

Aetiology

Acute bronchiolitis is rarely seen except when influenza of a respiratory type is epidemic. It is not limited to any age group, but it is in children under the age of 2 years that its attack may be so often overwhelming. This may depend on a defective local resistance in the absence of any acquired immunity; often another factor appears to be the heightened virulence of an invading organism in its passage through several hosts, for the baby is usually the last member of the household to contract a catarrhal infection.

It is most often seen in children of the poorer classes, and here the lower immunity presumably depends on environmental factors: defective and injudicious feeding, confined living-space, and closer contact with infections. Middle-class children by no means escape, however, and the most rapid death in this series (thirty-six hours from the onset) was that of the son of a professional household whose nature and nurture were ideal.

No influenza-A virus was recovered by the Medical Research Council workers (C. H. Andrewes, in a personal

communication) during the 1940 epidemic, with the exception of one specimen brought back from the army in France. It will be remembered that Stuart-Harris, Andrewes, and Smith (1938) attempted a clinical differentiation of influenza, in which their virus was recoverable, from "febrile epidemic catarrhs," in which it was not. One of the clinical distinctions suggested was the much greater incidence of acute bronchiolitis in virus influenza. Further investigation has demonstrated that no such clinical differentiation is possible (Stuart-Harris, Smith, and Andrewes, 1940), since most of the clinical criteria, including acute bronchiolitis, occurred commonly in the non-virus epidemics of 1939 and 1940. Large numbers of throat swabs were examined by one of us (G. R. O.) in the 1940 epidemic, but the findings were too inconstant to assume that the epidemic was due to the organisms demonstrated by the usual methods of smear and culture. Pneumococci (not belonging to Group 1, 2, or 3), fusiform bacilli and spirochaetes of Vincent, Gram-negative diplococci of the *catarrhalis* group (later meningococci also), and streptococci (*viridans* and haemolytic) were the organisms most commonly found. The variable findings soon led to the belief that these swabs were only demonstrating secondary invaders. Unfortunately we did not succeed in getting a case within forty-eight hours of the onset to send washings for examination for virus. All cases coming to hospital had, after the onset, been sick outside for over two days.

Morbid Anatomy

The main features of the histopathology of influenzal virus-infection in experimental animals are described in somewhat similar terms by the different investigators. Straub (1937) states that the primary lesion in mice infected with human influenza virus is a fibrinoid necrosis of the epithelium of the terminal and respiratory bronchioles leading to a state of complete epithelial desquamation. He gives a photomicrograph of an acellular fibrinoid plug in a bronchiole, and states that the exudation of polymorphonuclear leucocytes is not a feature unless secondary infection takes place. Other investigators do not refer to a "fibrinoid" exudate. Shope (1934) describes the bronchial exudate in ferrets infected with the swine influenzal virus as "a thick, tenacious, glassy, white mucous exudate which is usually profuse." He finds large numbers of inflammatory cells in the walls of alveoli, but the air sacs themselves contain coagulated plasma and very few cells. Shope and Francis (1936) find a similar picture in the lungs of swine infected with human influenza virus. The cut bronchi show a less abundant glassy, tenacious mucous exudate. There was epithelial damage and a pronounced peribronchial round-celled infiltration. The alveolar walls were much thickened, but there were few cells in the alveoli. Nelson and Oliphant (1939) studied the development of the lesions in mice infected with human virus. Like other observers they find the earliest lesion (eighteen to twenty-four hours) is damage to the bronchial epithelium, but there is an exudate in which polymorphonuclear leucocytes predominate. By forty-eight hours the polymorphs become necrotic and epithelial damage is more severe. The interstitial alveolar exudate appeared in three days, and this was the time the animals began to die.

The essential features of experimental influenza may therefore be summarized thus: (1) more or less complete destruction of bronchiolar epithelium; (2) obstruction of the lumen of bronchi and bronchioles by a plug of "thick, tenacious, glassy, white mucous exudate"; (3) peribronchiolar cellular infiltration extending to the interstitial tissue of some of the neighbouring alveoli; (4) alveolar sacs mostly free from exudate, but some close to affected bronchioles contain a serous exudate with few cells. These essential features were all present in the necropsies now to be described, and this is part of the justification for regarding them as truly influenzal.

During the 1940 epidemic in Derbyshire opportunities for post-mortem examination occurred in a number of cases. Two of these were especially interesting because they were almost pure acute bronchiolitis.

A boy aged 1 year and 7 months died in the Derbyshire Hospital for Sick Children; the necropsy was made on February 1, 1940. The pharynx and trachea showed simple reddening with no membrane and little exudate. The lungs were markedly emphysematous; they did not collapse when the chest was opened, but met in front of the heart. There was no pleural exudate. The cut surface of the lungs did not show any obvious pneumonic consolidation—the general emphysema gave the reverse appearance. Small pearly nodules very closely resembling miliary tubercles stood up all over the cut surface. They were not as numerous as in most cases of miliary tuberculosis: there were no tubercles elsewhere in the body, and acid-fast bacilli were absent. The nature of these "tubercles" is shown in the photomicrographs. Fig. 1 (see Plate) shows the lumen of a bronchiole 0.7 mm. in diameter. It is plugged with tenacious mucus in which only a few cells are present. The epithelial lining is completely necrotic and the wall is infiltrated with polymorphs, lymphocytes, and macrophages. Most of the alveoli near this bronchiole are overdistended with air, but in one part inflammatory changes have taken place; these are interstitial engorgement and infiltration and a serous exudate into the alveolar sacs. This mucous plugging and epithelial destruction was the typical lesion in the larger bronchioles; some contained rather more pus. Fig. 2 shows the changes in the smaller respiratory bronchioles. This bronchiole is seen to be plugged with a cellular exudate obviously different from the plug of mucus just described. The cells in the exudate are necrotic polymorphs with pyknotic nuclei and macrophages which are well preserved. Changes in the surrounding alveoli are similar to those shown in Fig. 1. A number of sections were examined after staining by Gram's method, but no organisms could be found. The remaining organs in this child showed nothing of interest.

Fig. 3 is from a woman aged 36. Necropsy was performed on February 29. The lungs were both markedly emphysematous and showed no pneumonic consolidation. The lesions were virtually the same as in the baby. This photomicrograph shows a small bronchus with cartilage. There is some necrosis of the lining epithelium, cellular infiltration is relatively slight, mucous glands are secreting freely, and the lumen is blocked by a plug of tenacious white mucus with very few inflammatory cells. The diagnosis before death in this case was influenzal bronchitis (not pneumonia), and dyspnoea and cyanosis were prominent features.

A third case may be mentioned because the patient, a man aged 50, died on February 21, 1940, less than an hour after an injection of morphine. His lungs were markedly emphysematous and met over the heart; the right weighed 19 oz. and the left 20 oz. There was no obvious pneumonic consolidation, but the bronchi were blocked by muco-purulent plugs. His other organs were healthy, but the heart weighed 16 oz. and showed early coronary arteriosclerosis.

The main difference between the lesions in these human cases and those in the experimental animals is the extent of the emphysema. Jackson (1934a) describes four types of bronchial obstruction by foreign bodies and exudates. In the "by-pass valve" ingress and egress of air are checked but not prevented, so there is no collapse or emphysema of the lung. In the "check-valve" type air can enter, but the egress is stopped, and this results in emphysema. The third type is a "stop-valve" which causes obstructive atelectasis. The fourth type is really a variant of the third type—a ball-valve obstruction allowing egress only, which results in rapid and complete atelectasis as in the "stop-valve" effect of Type 3.

In view of the great clinical importance of these plugs of mucus it would be interesting to know how they arise. Cartilage disappears from bronchi when they reach a diameter of about 1 mm.; the tubes smaller than this are known as bronchioles. Some state (e.g., Maximow and Bloom, 1934) that the mucous glands disappear with the cartilage. Others (e.g., Lewis and Stohr, 1913) state that glands may extend beyond the cartilage and that goblet cells may be found until the ciliated columnar epithelium gives way to cuboidal and then respiratory epithelium. Miller (1940) states that cartilage disappears when the diameter reaches 0.6-0.7 mm. and that goblet cells become less as the diameter falls and disappear in bronchioles of about 0.4 mm. However this may be, it is notable that plugs of mucus are found in bronchioles much smaller than those which are said to have mucous glands. Was this mucus secreted by the epithelium before it was destroyed, or was it secreted by glands in larger bronchi?

Signs and Symptoms

The onset may be acute, with fever, very rapid and laboured breathing, cyanosis, severe cough, and prostration; but more often the child has for a day or two a slight temperature, pharyngeal cough, and some gastro-intestinal upset before the infection extends. The larynx may next be affected; the child develops a laryngeal cough together with soreness over the larynx, hoarseness of the voice, and sometimes aphonia. Dyspnoea and stridor, due to laryngeal spasm, may be present at this stage. From this phase the child may pass quite suddenly to bronchiolitis. The ultimate bronchioles become plugged with exudate and the clinical picture is dominated by *obstructive dyspnoea*. Respiratory distress is then very marked; the respiration rate is rapid—from 60 to 100 a minute. There is recession of the soft parts of the chest during inspiration. Cough is always incessant and disturbing. Cyanosis is often obvious quite early, but becomes extreme towards the end. Collapse is usually terminal, but sometimes the toxaemia appears to be profound from the start and the child is quickly apathetic and stuporous. The characteristic clinical picture is distressing and unforgettable: the head turning restlessly from side to side on the pillow, the dusky cyanosis of the lips and cheeks, the expression concentrated but unprotesting, the wildly distressed breathing, the relentless cough, and the final apathy. The physical signs are dominated by the presence of fine rales scattered over both lungs and, particularly towards the hila, mingled occasionally with coarser rales. The air entry is everywhere diminished, but there is no evidence of consolidation. The percussion note is more resonant than normal owing to the emphysema which is usually present. Sometimes sibili accompanying prolonged expiration may be heard, suggesting the presence of bronchiolar spasm. Occasionally large areas of collapse at the base may be suspected, presumably due to the blocking of large bronchioles with exudate. The degree of local emphysema or collapse presumably depends on whether the obstruction is of the "check-valve" or the "stop-valve" type.

The course varies considerably. A child acutely ill may be well and without symptoms in three days. Death from obstructive dyspnoea occurs, if at all, on the second, third, or fourth day. More often the fine rales give way to the coarse rales of an ordinary bronchitis when the acute phase is over, and this may persist for a few days. Sometimes consolidation develops and a protracted broncho-pneumonia sets in; occasionally a whole lobe is consolidated. The recovery of the urgent and severe cases with obstructive dyspnoea appears to depend on the institution of the measures detailed below.

Treatment

A student examining the measures advised by a score of authorities for the treatment of acute bronchitis and bronchopneumonia in children will find opinions so various that he may doubt if a multitude of counsellors achieves wisdom. He will discover that on such questions as fresh air, hydrotherapy, steam tents, oxygen, alcohol, digitalis, emetics, stimulants, mustard baths, plasters, poultices, venesection, blood transfusion, sedatives, and cough-mixtures there are as many opinions as authors. Abt (1939) represents mature opinion when he writes of the treatment of pneumonia in children: "We have long believed that one form of symptomatic treatment was as good as another provided neither form did harm."

One of the general methods to be adopted in the treatment of acute bronchiolitis is that these children should be nursed in warm moist air, with an adequate oxygen supply. In gamgee jackets, in antiphlogistine, and in linseed and mustard poultices it is difficult to put faith, but it is more difficult still to withstand the expectations of nurses and parents. Alcohol is the best sedative for children (and phenobarbitone the second-best). Brandy, whisky, or port may be used for children; doses may be individually determined, but 30 minims to 1 drachm two or three times in the twenty-four hours is an adequate dose for a child of 1 year. *No other sedative should be used for children with acute bronchiolitis, for if by sedatives their respiratory excursions are depressed and their coughs are quieted they die: any derivative of opium may bring a sleep which is final.*

"All bronchial therapy is futile," wrote the great Osler, dying of an influenzal infection; and this death-bed pronouncement has a papal quality. Moreover, there is to-day no need to resort for help to the Virginian prune, the wild lettuce, or ipecacuanha. Least of all to ipecacuanha: children are either not ill enough to justify the use of it in emetic doses or are too ill for this to be a wise therapy. In the treatment of acute bronchiolitis there are four factors demanding separate consideration—the infection, the obstructive dyspnoea, the cyanosis, and the collapse.

The Infection

It is important to use sulphapyridine (M & B 693) in full dosage, and to use it quickly. Infants 1 year old who are acutely ill when first seen should be given 1 gramme (2 tablets) immediately and 1/2 gramme four-hourly in the succeeding twenty-four hours. It is necessary to continue with the sulphapyridine tablets for at least a week in gradually decreasing doses, otherwise the infection will in many cases relapse and a protracted bronchopneumonia may develop. If it does so it becomes obvious in the second or third week that the sulphapyridine is having no influence on the course of the infection. It may be necessary to give the sulphapyridine by intramuscular injection; 3 c.cm. of the injection being mixed with 3 c.cm. of normal saline, and particular care being taken to inject direct into muscle. This is not easy in infants, who have little muscle and much subcutaneous fat. Large and slowly healing areas of necrosis are a common sequel of careless administration. It is rarely necessary to employ intramuscular injection: children are not usually disturbed by the ingestion of sulphapyridine. Alkalis or nicotinic acid are effective in relieving nausea and vomiting. This therapy rests on the assumption that the bronchial invaders are sensitive to sulphapyridine. Certainly there was no doubt of this in the last epidemic. The infection was quickly under control, and if the child could be maintained through its period of obstructive dyspnoea for a short time the sulphapyridine usually did the rest.

INDICATIONS FOR SULPHAPYRIDINE THERAPY

What are the indications for the use of sulphapyridine in the acute catarrhal infections of childhood? This is a question to which many different answers may be given: it will be generally agreed that there is seldom evidence in children, even with considerable dosage, of extreme depression of granulopoiesis. These are some empirical suggestions for its employment:

1. It should only be used if the infection appears to be severe enough to justify a week's therapy.

2. It should be used more often in epidemic than in sporadic cases, in weakly and debilitated children than in the healthy, in catarrhal infections complicating measles and whooping-cough than in primary infections.

3. It should always be used in infections with an acute onset—i.e., convulsions or rigors or high temperatures.

4. It may be more safely omitted in lobar pneumonia than in bronchopneumonia.

5. There is only need for its urgent administration in acute infections. In less severe infections a period of observation for the mobilization of the host's resources seems rational. It is easier to justify delay than the use of desultory or half-hearted measures.

The Obstructive Dyspnoea

This is the most urgent symptom, and *steam* usually brings great relief. The majority of modern writers will have none of it; others allow a kettle in the middle of the room at some distance from the bed; and a few permit a half-tent over the head of the bed. Steam-tents are the antithesis of the fresh-air treatment of pulmonary infections; but what proved virtue has fresh air besides its oxygen content? Those writers who believe that "fresh air has a stimulating effect on metabolism" are very careful to warn against air that is too fresh—i.e., a draught—and they temper their enthusiasm for alfresco therapy with warnings against the vagaries of the British climate. Moreover, where is this fresh air in an oxygen tent? There is no need to be afraid of surrounding the child with an atmosphere of steam: it is soon obvious that the patient's dyspnoea is relieved. The steam-kettle should be used with its nozzle inside the tent for periods of half an hour, and the child should be replaced in steam whenever breathing becomes difficult.

If there appears to be any bronchial spasm exaggerating the obstruction 2 minims of adrenaline (1 in 1,000) should be used and repeated. Otherwise, 1/150 grain of atropine, repeated four-hourly, seems helpful in decreasing the bronchiolar exudate.

We have no experience of bronchoscopic aspiration in this condition, nor any knowledge that it has been used in this country. Chevalier Jackson (1934b) writes thus of the kindred condition which he calls "self-drownage": "The accumulation may literally drown the patient in his own secretions. This is illustrated frequently in influenza and arachidic bronchitis. Infants cannot expectorate, and their cough reflex is exceedingly ineffective in raising secretion to the larynx. The cough reflex may be entirely absent in children. Age may be cited as one of the most frequent etiologic factors in the condition of self-drownage. Bronchoscopic aspiration is quite efficient, and can save any patient not affected with conditions that are fatal by other pathologic processes." Bronchoscopic aspiration under these conditions requires the services of an expert bronchoscopist who is accustomed to bronchoscopy in children without general anaesthesia.

The Cyanosis

Cyanosis is the indication for oxygen, which should be delivered through a Woulfe's bottle of warm water and a nasal catheter at the rate of three litres a minute for an infant (a rate of flow which is a continuous stream, making the water splash in the Woulfe's bottle). The nasal catheter is to be preferred to the small oxygen tent in acute bronchiolitis, for delivery by nasal catheter has the advantage that steam can be employed at the same time. The oxygen should be used continuously as long as the cyanosis persists and not, as is often recommended, for a few minutes every hour.

The Collapse

No measures devoted to preventing or relieving circulatory failure have the same importance as those already described. There is no drug which re-energizes the failing heart nor any which has a selective action in an overcharged venous system. Coramine is the drug which seems best to stimulate the failing circulatory system, and should be used for a child of 1 year by intramuscular injection in 0.5 c.cm. doses every four hours. Strychnine, adrenaline, camphor, digitalis, strophanthin, and eucortone all have their advocates. It is difficult to assess these last-minute remedies that are intended to arrest the patient's progress from the "saddle to the ground." Most often they appear to delay this progress rather than to check it finally; perhaps they are best regarded, in a friend's indulgent words, as "house-physicians' treatment." Some of them may be definitely harmful and are better avoided. Venesection is frequently recommended for right-sided heart failure; one paediatrician commends the withdrawal of "a drachm or two of blood from a vein as a most useful measure and one that is probably not employed often enough." It would certainly need to be used very often in this measure to make any difference to an overcharged circulation. Nothing less than the removal of 50 c.cm. would seem likely to give any relief to a child with a blood volume of more than twelve times this quantity. In cyanosed children with distended jugular veins it has definitely appeared to be of value, especially if the blood is removed rapidly from the circulation.

Summary and Conclusions

It is contended that acute bronchiolitis is the essential pulmonary lesion in epidemic influenza, as it is in experimental influenza. This condition is particularly common in young children, in whom it produces urgent dyspnoea and, if not vigorously treated, death by asphyxia.

The clinical picture and the morbid anatomy of the condition are described. It is suggested that the respiratory obstruction is caused by mucus in the bronchioles. The lungs of an infant showing this condition are described and illustrated.

Sulphapyridine, steam, and oxygen are the essential therapeutic measures. Bronchoscopic aspiration in the hands of the expert may be life-saving.

The use of any sedative demands especial watchfulness: opium or its derivatives bring swift disaster.

We are indebted to Dr. E. P. L. Hughes for permission to review some of his case notes and also to Detective-Sergeant J. S. Fayers for the photomicrographs.

EXPLORATION OF THE COMMON BILE DUCT FOR STONE

DRAINAGE WITH T-TUBE AND CHOLANGIOGRAPHY

BY

MICHAEL J. SMYTH, M.Ch., F.R.C.S.

Surgeon, E.M.S.; Surgeon, Hospital of St. John and St. Elizabeth, N.W.8

(WITH SPECIAL PLATE)

In the early days of operations for cholelithiasis the majority of surgeons were content to remove the stones and drain the gall-bladder. The operation was comparatively easy and, as operations went in those days, comparatively safe, and it was regarded as the ideal surgical treatment. Not all surgeons, however, accepted this view, and there were not wanting restless intrepid spirits who did not hesitate to remove the gall-bladder if it was obviously diseased; but even they viewed with misgivings any condition which necessitated interference with the common bile duct. Their reluctance was due not so much to the added difficulties of the operation as the fear that if an actual fatality did not result they might be left with a persistent biliary fistula. Too often had they encountered fistulae following on drainage operations of the gall-bladder, and the thought no doubt was uppermost that a fistula, almost inaccessible if not irremediable, might result. Consequently the pioneers of operations upon the common bile duct were at great pains to secure a watertight closure of the duct, and as a further precautionary measure they closed the abdomen without drainage. Complete closure was found to be a mistake, for in spite of their efforts there was leakage of bile, with fatalities due to peritonitis. This danger was averted by insertion of a drainage tube down to the suture line, and it was found that the duct healed satisfactorily. Indeed, it was soon evident that, provided the duct had not been grossly damaged, it required little suturing. Some even went so far as to omit suturing altogether, with no untoward result; in fact, the danger of fistula was more imaginary than real, and if a temporary fistula were required for hepatic drainage, then it was necessary to stitch a tube in the duct itself, the duct again closing rapidly when the tube came away.

Granted the remarkable healing powers of the common bile duct; yet it has always been a most debated step among surgeons as to whether or not exploration of the duct should be carried out in *all* operations for cholelithiasis. It adds to the time and gravity of the operation, since it is performed at depth—sometimes at great depth and with great difficulty. Obviously if the duct contains a stone it must be removed, for cholecystectomy will not rid the patient of his trouble: as well might one lock the stable door when the horse has bolted. It is in cases, however, in which there is little or no indication for exploration of the duct or in which the surgeon is in doubt as to whether he is dealing with an impacted stone, an enlarged gland, or a thickened portion of pancreas, that controversy arises. There are those who affirm that the duct should be explored in all cases in which operation is undertaken for cholelithiasis or cholecystitis, and they produce statistics to prove their point. Statistics, as someone has remarked, may be made to prove anything, even the truth, but much evidence is accumulating to prove the contention that this step should be more often carried out. In many instances where patients have had their gall-bladders removed they have not been completely relieved of their sufferings, and indeed to their great disappointment sometimes have a return of symptoms in all intensity. This is due to stone in the common bile duct that has been overlooked or neglected. If not due to actual stone, the advocates of common bile duct exploration say it is due to biliary mud or inspissated mucus, which could have been remedied by drainage of the duct and dilatation of the sphincter of Oddi, a muscle which they maintain is always in spasm in such cases. A second operation is not welcomed by the patient or the surgeon, for it is more difficult and more dangerous.

Surgeons are well aware of the added difficulties and dangers of common bile duct exploration, but Lahey of Boston, who is a strong advocate of this step, thinks that with a surgeon of competence and experience in biliary surgery this step does not entail any more danger to the patient—in fact, quite the contrary. In a large series of cases in which he or his colleagues of the Lahey Clinic have explored the common bile duct, only one patient in whom no stones were found died following exploration. On the other hand, the mortality from secondary operations for stone in the duct was out of proportion. He further warns against too much reliance being placed upon clinical features which heretofore were regarded as a *sine qua non* of stone in the common bile duct. The following summary embodies most of his findings.

Clinical Features of Stone in Common Bile Duct

Jaundice.—This symptom, which was considered a sheet-anchor in diagnosis, is absent in at least one-third of cases. Lahey in a review of three separate series of cases in which stones were present in the common bile duct found that jaundice was absent, and never had been present, in not less than 37 % of cases—in his last series 39 %. Snell of the Mayo Clinic lays emphasis on the fact that stones in the common bile duct rarely if ever completely occlude the duct for long, and so the stools or duodenal contents always contain bile at one time or another. On the other hand, an evanescent jaundice associated with colic and cholelithiasis does not necessarily mean a stone in the common bile duct, as it may be due to hepatitis or mild cholangitis.

Colic.—From 75 to 80 % of patients suffer from upper abdominal colic at some stage of the disease. This means that at least 20 % do not have acute pain, though they may suffer perhaps from indigestion, with intolerance to certain foods, such as eggs, fats, and so on. It is stated that the colic is most often referred to the right upper abdominal quadrant, but in my own experience of eight cases in which stone was found only in the common duct the pain was referred to the epigastrium and radiated through to the back between the shoulder-blades.

Chills and Fevers (Charcot's Intermittent Hepatic Fever) due to Cholangitis and Hepatitis.—In Lahey's series chills and fevers were present in only 4.2 % of cases—a remarkably low figure which was attributed to the fact that a large proportion were operated upon early, and also to the practice of exploring the ducts in all biliary operations.

Duodenal Drainage.—Aspiration of the duodenal contents in Lahey's series yielded crystals of calcium or cholesterol in the drainage sediment in 30 out of 32 cases in which stones were found in the common bile duct at operation.

X-Ray.—Cholecystography is indirectly most helpful, but of course the dye does not outline the common duct. Sometimes if the stone in the duct contains enough calcium it may be made to show up and its position be located by the aid of barium in the duodenum.

Indications for Exploration of Common Bile Duct

At operation the following findings are suggestive of stone in the common bile duct: (1) Thickened and contracted gall-bladder. (2) Dilated cystic duct: normally the duct admits a probe with difficulty. (3) Dilated common duct (normally a quarter of an inch in diameter) which has lost its colour. Even in the presence of enormous

dilatation, as sometimes happens in carcinoma of the head of the pancreas, the duct will retain its bluish colour, but when dilatation is associated with stone and infection it alters to a pinkish grey or yellow.

Among my own cases there were eight in which stones were found only in the common bile duct. In five of these the gall-bladder had been removed at a previous operation. All these patients suffered from intermittent colic, the pain being referred to the epigastrium with radiation between the shoulder-blades. The pain was not referred to the right hypochondrium. In one case in which the common bile duct had been explored six months previously by a competent surgeon the severity of the colic combined with rigidity of the abdominal muscles led to a diagnosis of perforated ulcer; at operation the tissues surrounding the duct were oedematous and somewhat bile-stained, and a good-sized stone was found in the duct. Six of the patients complained of jaundice, but the other two remained free from this symptom throughout their illness. The gall-bladder in each of the cases in which cholecystectomy had not been performed was unmistakably pathological—shrunken, with thickened walls and altered colour—and the cystic duct in each was widely dilated as if its passage had just been forced by a stone. The gall-bladder in one case was no bigger than the terminal digit of a medium-sized finger, and would barely have accommodated the stone which it had apparently expelled into the common duct.

At operation the ducts must be palpated carefully for stone. The index finger of the left hand is passed into the foramen of Winslow and the duct carefully examined with finger and thumb, aided by the fingers of the right hand in front. Some surgeons prefer to carry out this examination standing on the left side of the patient, reversing the position of the hands for examination. If after careful palpation the operator is still in doubt bile should be withdrawn from the duct by a hypodermic syringe. Normal bile is clear, is golden yellow in colour, and stones will not be found associated with it. On the other hand, if bile is black or cloudy or contains flocculi, stones will rarely be absent from the duct.

It is unnecessary here to give the surgical technique of exploration of the common duct in detail. I do not use a bridge to elevate the costal margin, as anaesthetists find that it causes a fall in the blood pressure. It is better to explore the common duct through a separate incision than to attempt to explore through the severed end of the cystic duct. A suction apparatus should be in use, and, in addition to the usual packs, a small gauze pack should be inserted in the foramen of Winslow to prevent leakage into the lesser sac. Not only should the common bile duct be explored, but also both hepatic ducts for stones which escape upwards. This examination is done with a scoop or a Desjardins forceps. Elusive stones can sometimes be evacuated by flooding the ducts with saline and coaxing the stone towards the opening by means of the suction-tube inserted into the duct. Bougies should be passed down the duct to ascertain if the opening into the duodenum is patent, and dilatation of the sphincter of Oddi should be gently carried out with bougies—silk-web olivary bougies for preference, though some prefer to use Lister's sounds. Bougies greater than size 12 English or 22 French should not be used, for fatalities following excessive dilatation have been recorded. It may be added that the presence of the bougie in the lower end of the duct often materially aids palpation and helps to distinguish whether the particular swelling is inside or outside the duct.

It must be acknowledged, however, that even after the most careful exploration of the common bile duct by competent surgeons stones in the duct have been missed. There is, of course, the possibility that such stones have formed in the bile ducts themselves after the gall-bladder has been removed. The generally accepted view, however, is that stones are formed in the gall-bladder and pass on via the cystic duct to the common duct. Some hold opposite views and believe that stones originate—the nucleus of the stone, at any rate—in the intrahepatic ducts. The composition of gall-stones and the site of their formation, then, are not of purely academic interest.

Naunyn first advanced the theory that cholesterol stones were formed in the gall-bladder and that for their formation infection and stasis were necessary. In recent years his views have been ably supported by Sir James Walton, a surgeon of great experience. Aschoff and Baemeister maintained that a pure cholesterol stone is formed independently of infection, but that infection is necessary for the formation of a mixed stone. Boysen held the view that in all gall-stones there was a nucleus of pigment calcium, even in the so-called pure cholesterol stone. He had found small pigment-calcium stones in wholly normal gall-bladders, but cholesterol stones in inflamed gall-bladders. Rovsing agreed with Boysen that the primary factor was the formation of bilirubin-calcium stone, not in the gall-bladder, however, but by precipitation of bilirubin calcium in liver cells.

Lahey has recently added great support to the theory that stones can be formed in the ducts. He is convinced, from an experience amounting to 2,177 patients operated upon for gall-stones, that most common and hepatic duct stones are not produced in the gall-bladder but originate primarily within the common and hepatic bile ducts. "Again and again," he states, "have we found and removed stones in the common bile duct when the cystic duct was so small that even the smallest stone of bird-shot calibre would have trouble in passing through it." Rufanov (quoted by Walters) collected 57 cases of formation of stones within the intrahepatic ducts that had been reported in the literature, and reported 5 of his own.

Flint records an interesting case of a man who had four operations for biliary colic with jaundice and at each operation a pigment stone (or stones) was found in the common duct, the gall-bladder having been removed at the first operation. At the fourth operation the spleen was twice the normal size. Splenectomy rid the patient of his trouble, and he was alive and well fifteen years afterwards.

Cholangiography and T-tube Drainage

In recent years a method of visualizing the bile duct—cholangiography—has been introduced, a method which may in time solve this vexed question. An opaque solution is introduced direct into the common bile duct and a radiograph taken. Any stones in the duct show up as filling defects. This method can be utilized at the time of operation (immediate cholangiography) or the solution can be introduced later through the tube which has been used for drainage of the common bile duct (delayed cholangiography). Immediate cholangiography, which has been strongly advocated by Best, necessitates special *x*-ray arrangements in connexion with the operation table, and the surgeon must wait while the negative is being developed. A needle and 20-c.cm. syringe are used for injecting the opaque solution after the bile has been aspirated from the common bile duct. This ritual will hardly appeal to surgeons who are confident of finding stones in the common bile ducts without the aid of new-fangled methods, but even the most competent operators can be safeguarded against error if they will adopt the principle of using a T-tube for drainage on the common duct and carrying out cholangiography afterwards. The ordinary straight drainage tube used by surgeons is retained in the duct by a suture of plain catgut, as chromic gut has on occasions been found to provide a nucleus for stone formation. Plain gut dissolves in the course of

six to ten days, when the tube comes away. This period is inadequate for drainage in cases in which there has been cholangitis and hepatitis. A T-tube can be retained until the liver function has been restored to normal, and, furthermore, after an interval of twelve days, when the tube is firmly surrounded by the healing tissues, cholangiography can be carried out. If a stone has been overlooked and is discovered on *x*-ray examination it does not necessarily mean a further operation. There are now means at our command, through the aid of the T-tube, which may help to rid the patient of the stone without operation. The T-tubes supplied by manufacturers are invariably out of proportion, the cross-piece of the T being longer than the common and hepatic ducts combined. The whole circumference of the cross-limb is unnecessary,

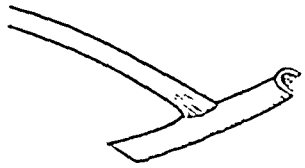

FIG. A.—T-tube prepared ready for use.

half the circumference being quite sufficient. This part of the tube should be whittled down until it measures no more than 1½ inches in length at the outside and half the circumference of the tube removed, for all that is required is a projecting shoulder on each side of the main stem to retain the tube in position (Fig. A). When prepared

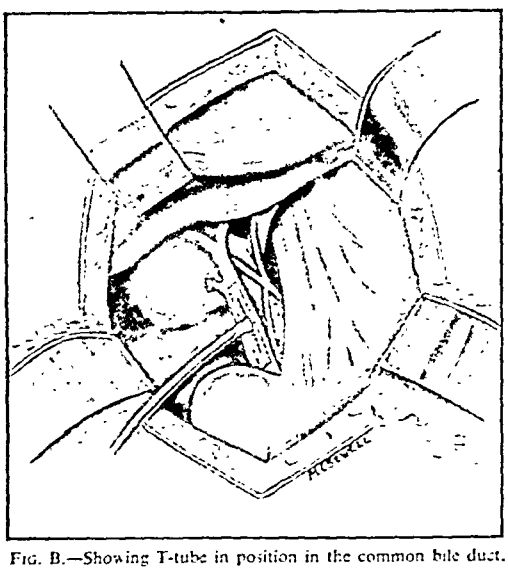

FIG. B.—Showing T-tube in position in the common bile duct.

in this way the tube is easy to introduce and is readily removed without causing the patient discomfort. The opening in the common bile duct is closed snugly around the tube and no stitch through the tube is necessary (Fig. B). An excellent type of tube is that used by Maingot, but, failing such, the operator can fashion one as described.

It is not expected, of course, that the T-tube should act as a drain for the operation area; this is provided for by a second tube which reaches down to the common duct and which for preference is brought out through a separate stab wound as recommended by Rendle Short.

The opaque solutions or contrast media most favoured have been thorotrast and lipiodol. I have already in this journal pointed out the objections to the use of these solutions. Thorotrast may be dangerous on account of its radio-active properties, and lipiodol, being thick and oily, does not mix well with bile and so filling defects may be mistaken for stones. I have tried uroselectan, but it is too apt to cause pain. Perabrodil I found quite satisfactory (see radiographs reproduced in Plate). To get the full opaque effect of the solution bile must first be aspirated from the common bile duct through the T-tube. The solution is first warmed to 100° F., then introduced from a sterile syringe. The usual amount introduced varies from 10 to 20 c.cm., about 15 c.cm. being the average, but in some cases in which the ducts were more than usually dilated -cases of cholangiectasis and hydrohepatosis—I have used as much as 35 c.cm. The injection is stopped as soon as the patient complains of discomfort in the epigastrium, and a radiograph is taken.

If stones are discovered by cholangiography the following methods of dealing with them are tried before a second resort to operation. Bile is first aspirated, then 1 to 2 c.cm. of ether is introduced and the tube is left open so that the ether, which readily vaporizes at body temperature, may not cause too much pressure within the duct. It is hoped by this means to dissolve the stone. Treatment can be repeated several times daily. Pribram, who has tried this method extensively, claims much success for it (stones dissolved in 38 cases). Walters and Wesson advise the addition of alcohol to dilute the ether, as well as the administration of amyl nitrite to produce dilatation of the sphincter of Oddi. In this way they were successful in fragmenting a stone which had been impacted in the ampulla of Vater and securing its passage into the duodenum.

By means of opaque media it is possible to study the effects of different drugs on the sphincter of Oddi. Amyl nitrite and nitroglycerin produce the greatest dilatation. Magnesium sulphate and fats, cream, olive oil, etc., also dilate the sphincter, but atropine is uncertain. Morphine, codeine, and dilaudid, contrary to what might be expected, produce spasm of the sphincter. Walters and others at the Mayo Clinic studied particularly the effect of morphine in 9 cases of biliary colic after the gall-bladder had been removed, and found that 1/6 grain of morphine sulphate produced pain, which was completely relieved by 1/100 grain of glyceryl trinitrate or by inhalation of amyl nitrite. Spasm of the sphincter of Oddi is probably the cause of clay-coloured stones observed in some cases after the administration of morphine. Best of Omaha, who had not had much success with the ether method, put these findings to good account in a number of cases. He combined the use of nitroglycerin, atropine, magnesium sulphate, and olive oil by mouth with the introduction of warm olive oil into the common bile duct through the T-tube.

I have tried the ether method without success, but in one case continued treatment on the lines laid down by Best, and was eventually successful in ridding the patient of her symptoms. The following is a brief history of the case.

A female patient, previously operated upon by another surgeon, when the gall-bladder, which contained stones, was removed; common bile duct not explored. Three months later recurring colic. Second operation (by me)—three stones removed; thought that another stone could be felt in the right hepatic duct further up, but all search proved unavailing. Bougies passed through ampulla into duodenum, and sphincter of Oddi dilated. T-tube inserted. Radiograph twelve days later: filling defect ampulla of Vater. Ether method tried unsuccessfully. Patient unfortunately had to be

evacuated from hospital and the T-tube was removed. While awaiting admission to another hospital she continued on treatment with nitroglycerin, atropine, magnesium sulphate, and olive oil. A few days before she was due to be readmitted to hospital she sustained severe colic followed by slight jaundice, and since then—now more than a year ago—has had no further trouble. I have no doubt that her attack signalized the passage of her stone into the duodenum.

How Long to Retain the T-tube

The question arises how long the T-tube should be retained in the common duct. One reads of cases, in America, in which it has been retained for periods varying from three months to a year. The time to remove the tube is when the concentration of bile salts in the bile has returned to normal. Following operation, whatever the condition of the liver, the concentration of bile salts falls for the first five days, a fall that is more pronounced if chloroform is the anaesthetic employed. The best anaesthetic would seem to be gas, oxygen, and cyclopropane. Febrile reaction following operation delays the return to normal. Unless the liver has been severely damaged by inflammation and back-pressure, the concentration of bile salts reaches normal about the fifteenth day, after which time it is safe to remove the tube. On the other hand, in cases in which there has been prolonged continuous or intermittent jaundice, particularly if associated with fevers and chills, it will be found that the concentration of salts will be delayed, and the tube may have to be retained for a much longer period as above mentioned.

I must offer a word of warning here against too prolonged and continuous drainage. In the case above recorded there was partial obstruction to the flow of bile into the duodenum. The tube was left to drain continuously, with the result that practically all the bile escaped externally; the patient at one stage showed rapid deterioration, and it was only by the use of intravenous saline and glucose and the administration of bile salts (veracolate) by mouth that we were successful in restoring her condition. Where there is not complete obstruction the tube should be closed at intervals to allow the bile salts to escape into the duodenum. If there is complete obstruction and the bile drains only externally, it is necessary to administer bile salts by the mouth and keep the patient as well as possible by other means until such time as a short-circuit or other operation can be done to divert the bile internally.

Jaundiced Cases

A certain proportion of surgeons have always been chary about operating upon jaundiced patients, because of the danger of haemorrhage—not vigorous haemorrhage from any particular arteries, but a continuous steady ooze from the tissues which is apt to continue after operation in such cases. This lack of clotting power is due to prothrombin deficiency and can be corrected by giving vitamin K in combination with bile salts by mouth before operation, the bile salts being necessary for the absorption of the vitamin from the intestine. Vitamin K for oral administration is supplied under the trade name of clotogen (Abbott). Another preparation—kapilon (Glaxo)—can be given by intramuscular injection. American writers, Whipple and Rhoads particularly, speak enthusiastically of this treatment, which can be enhanced by a blood transfusion before operation.

I believe that the danger of haemorrhage in jaundiced cases has been very much exaggerated—so much so, in fact, that in the minds of many newly qualified men there exists an almost superstitious awe of the consequences of surgical intervention. Personally I have never seen a case of jaundice in which a fatal ending could be attributed solely to haemorrhage following operation. No doubt such cases do occur, but some of them must be due to gross neglect of haemostasis. What does contribute more than anything else to a fatal ending in these cases is lack of adequate preliminary treatment and perhaps the efforts of the surgeon to attempt too much at operation. There is no necessity, for instance, to remove the gall-bladder when the patient is very ill and the urgent need is for relief of obstruction to the common duct. The gall-bladder can be left for another day. Where possible the patient should be put on a diet consisting of 75% carbohydrate, 20 to 25% protein, and not more than 5% fat for seven to fourteen days before operation. In cases of emergency, or if the patient is nauseated or vomiting, intravenous saline with glucose 5 or 10% should be given by the drip method, combined with blood transfusions. For further details of treatment I cannot do better than refer the reader to Flint's (1937) excellent paper.

Summary

Stone in the common bile duct is more often overlooked at operation than is generally realized.

Indications for exploration of the common duct for stone have been outlined—clinical features as well as conditions at operation.

Too much reliance must not be placed on the presence or absence of jaundice as a symptom. At a conservative estimate jaundice has been found to be absent in no less than one-third of the cases of stone in the common bile duct.

The use of a T-tube for drainage is strongly advocated, as it can be retained longer than the ordinary straight tube and so allows the liver a better chance of recovering to normal.

By means of the T-tube, (*a*) concentration of bile salts in the bile can be ascertained and an estimate be formed of liver function; (*b*) cholangiography can be carried out and any stones which have been overlooked detected; (c) treatment can be instituted to rid the patient of such stone without resort to further operation.

I wish to acknowledge my indebtedness to Dr. R. O'Donoghue and Dr. G. T. Loughborough for their kindness and help with the x-ray investigations.

The Bath Medical Book Society held its hundredth annual meeting on December 13, 1940. The society was founded for the purpose of circulating some of the recently published medical books; each member keeps a book a fortnight and passes it on to the next name on a list arranged so far as possible according to residence. The number of members is limited to twenty-five, and new members are chosen by ballot as vacancies arise. This small society fulfils a useful purpose in the medical life of Bath. Mr. A. Leonard Fuller has served as its honorary secretary for thirty-six years.

DIRECT DRAINAGE OF LUNG CAVITIES IN PULMONARY TUBERCULOSIS

BY

J. V. CUSSEN, M.B., B.Ch.

Medical Superintendent, Belgian Sanatorium, Montana, Switzerland

(WITH SPECIAL PLATE)

The direct drainage of lung cavities, introduced by Prof. Monaldi of the Forlanini Institute in Rome, would appear to offer interesting possibilities in the treatment of lung tuberculosis. Despite the constant improvement in the technique of the different methods of collapse therapy there remain many cases to which these methods cannot be applied. The direct drainage of a pulmonary cavity would seem to be a logical proposition, yet at first the idea of the transpulmonary drainage of a tuberculous cavity must cause some hesitation. The method and the theory on which it is based are founded on conclusions drawn from the work of Prof. Morelli on the mechanism of respiration.

Development of a Cavity

Two factors enter into the development of a lung cavity. The initial process is in the fine bronchioles or alveoli. Tubercles form which coalesce into consolidated areas. If the process is not arrested, caseation and softening, with involvement of the interstitial tissue, lead to the formation of a cavity. This is the first or biological factor. If it remains unchecked by the patient's resistance it will continue to predominate, leading to an extensive caseous process. However, in the great majority of cases the biological factor is modified and signs of defence are observed. Here the mechanical factor comes into play. Cavities, the dimensions of which may vary considerably from time to time, will often be observed in patients whose general condition is good and in whom there are but limited signs of activity. In these cases, in which the importance or variation in dimensions of the cavity would appear to be unaccompanied by proportionate signs of activity, the mechanical and not the biological factor seems to predominate. Poix and Vincent (1938) have studied these variations. The distinction is drawn between these cases and those in which the enlargement of the cavity is accompanied by signs of activity such as fever, increased cough, and sputum. The fluctuation due to the mechanical factor will be discovered radiologically and not clinically.

The traumatism to which a lung cavity is subjected during respiration has been studied by many. During the act of respiration the pressure exerted on the pulmonary parenchyma varies with inspiration and expiration. The lung is also in a state of constant distension. If there is a large drainage bronchus allowing free entrance and outlet the air pressure in a cavity will not be appreciably modified. If there is no drainage bronchus, or if the lumen is small or obstructed, the intracavernous pressure will be influenced during respiration. According to Monaldi, quoted by Arnould (1939), the partly obstructed bronchus will be found in the majority of cases. Even in the case of the large bronchus the passage of secretions can bring about intermittent obstruction. During inspiration the endocavernous pressure is diminished, whereas during expiration it is increased. The tissue surrounding the cavity is subjected to the opposing forces exercised by the expiratory process and the increased pressure in the cavity. The result is the development of atelectasis. The cavity is now less well protected from the traumatism caused by the thoracic traction and pressure during inspiration and expiration than if it were surrounded by healthy air-containing and elastic lung tissue. The increased traumatism leads to increased pressure on the pericavernous tissue, and so the atelectasis becomes still more pronounced. Monaldi has also drawn attention to the diminished circulation in atelectatic tissue. Reduced blood supply to the cavity hinders the patient's resistance and so facilitates the inflammatory factor.

The "fibrous ring" surrounding a cavity in relatively healthy lung tissue, sometimes alluded to in the interpretation of the pulmonary radiograph, would appear to represent atelectatic tissue and not fibrosis. It would seem clear that the permeability of the drainage bronchus plays a very important part. Some writers claim that it is an essential condition to the closing of the cavity. In fact, radiological observation shows that spontaneous closure is often preceded by the formation of an endocavernous fluid level. According to Corryllos, quoted by Arnould, the occlusion of the bronchus is followed by absorption of the air in the cavity, bringing about its diminution and closure. Nevertheless it cannot be readily accepted that the occlusion of the bronchus is essential. *X*-ray observation in a case of spontaneous healing will generally show that sputum diminishes in proportion to the diminution in the size of a cavity, and does not disappear until the cavity has finally closed.

A cavity must be possessed of a retractile quality if it is to close. The presence of atelectasis in surrounding tissue would appear to answer this need best. Post-mortem examination has proved the presence of pericavernous atelectasis. It may also be recognized in the radiograph. The rapid spontaneous closing of some large cavities would seem to be best explained by re-expansion of atelectatic tissue. The theory according to which the closing of a cavity is brought about by the contraction of fibrotic tissue has not been borne out by post-mortem findings. Rist and Rolland, quoted by Poix and Vincent, have described their post-mortem findings in the case of a large cavity which had completely closed. They found no evidence of fibrosis and no trace of the cavity. Similar observations have been presented by many others. Where fibrosis is observed it is usually star-shaped and does not correspond to the contraction of a fibrotic ring.

The disappearance of a cavity treated by an artificial pneumothorax maintained at negative pressures may be attributed to the re-expansion of collapsed alveoli. Collapse treatment has as one of its principal objects the elimination of respiratory traumatism, which, as has been seen, plays an important part in pericavernous atelectasis.

The cavity in which the mechanical factor has predominated is possessed of a retractile quality represented by atelectatic tissue. The cavity in which the biological element has been preponderant has not this quality. Such is the case in excavations in large caseous processes. The cavity in the advanced fibrotic lung also lacks this retractile quality, although the application of Monaldi's method to such cases will often show that there still remains a surprising possibility of retraction. The direct drainage of a tuberculous pulmonary cavity aims at combating the mechanical factor in the formation and maintenance of a cavity by producing a negative endocavernous pressure, facilitating the re-expansion of the peripheral atelectatic tissue, and so neutralizing respiratory traumatism. It seeks to overcome the biological factor by giving free outlet to inflammatory matter and debris and so deterging the surfaces of the cavity.

Drainage Technique

The instrument used consists of a trocar and cannula. The trocar is so constructed as to allow of the passage of

air between it and the cannula. The cannula has a lateral arm permitting its connexion to the manometer of a pneumothorax apparatus. The point of the trocar is but slightly bevelled.

If the technique of the method would appear simple, a strict attention to detail is essential. In the first place, it is of paramount importance to make sure that the lung is adherent to the parietal pleura in the region of the cavity. Only in the presence of adherent pleura may the method be applied. The extent of the adhesions must be such as to preclude all possibility of communication with an area where the lung is not adherent. Were this precaution not observed a pleuro-pulmonary fistula with all its consequences would be the result. The position of the cavity must be carefully studied by screen examination, as also on the radiograph. Tomographic plates will help towards a very precise location. The patient is placed preferably on an *x*-ray table permitting radiological control at each stage of the operation. The point of entry chosen will be between the anterior axillary line and the sternum, as this will best facilitate adoption of the recumbent position in the after-treatment. Most often the cavity is situated posteriorly, which is an advantage, as the drain will thus be introduced through healthy and elastic lung tissue. This will help to avoid the possibility of fistula and the escape of air around the drain. With the entry point decided on, the intercostal space is anaesthetized. The depth and position of the cavity are now controlled by the introduction of a long fine needle connected to a syringe. The syringe should be filled with fluid so as to avoid the possibility of introducing air into a blood vessel. As the needle is pushed gradually towards the cavity traction is made on the piston of the syringe. The free entry of blood into the syringe would indicate the presence of an important vessel. In this event the needle must be withdrawn and the entry point changed with a view to finding a less dangerous route. When the cavity is reached air can be drawn freely into the syringe. The direction of the needle is controlled by screen examination. If during the introduction of the needle no important blood vessel has been encountered the cannula may be pushed into the cavity. The direction and degree of penetration of the fine needle should be carefully noted before it is withdrawn. The track of the fine needle must be meticulously followed during the introduction of the cannula. While the cannula is being introduced the manometer is kept under observation. Small movements will be caused by the passage through alveoli. When the cavity is reached well-marked oscillations will be noted on the manometer. The correct penetration of the instrument may be controlled by the fluorescent screen. The trocar is now withdrawn. A suitable Nélaton catheter, No. 12, is introduced and the cannula is withdrawn carefully so as to leave the drain in position. The catheter is fixed to the chest by means of two strands of silk, twisted round each other and between which the drain is passed. The ends of the silk strands are fixed to the skin by adhesive plaster. A dressing is now applied, and the end of the drain is enveloped in the dressing.

The aspiration is not begun until twenty-four hours later. It may be effected by means of a small electric pump or a filter pump. The aspiration obtained by the difference of level between two vessels connected together, one of them filled with water, may be employed. This is an inconvenient method, as constant manipulation is necessary in order to maintain the difference of level. The electric pump is also suitable, but the apparatus tends to heat when used continually. The filter pump is the most convenient method of aspiration. The drain is connected to the aspirating apparatus shown in the diagram. It consists of a glass cylinder partially filled with water, approximately 75 cm. in length and 3 cm. in diameter. It is closed by a rubber stopper with two perforations, through which two glass tubes are passed. The short tube is connected to the closed aspirating circuit. The upper extremity of the long tube communicates freely with the atmosphere, whilst the lower extremity is plunged in the water of the cylinder. The degree of immersion determines the maximum depression desired. When the aspiration tends to become too strong atmospheric air is sucked through the long tube, thus limiting the negative pressure in the aspirating circuit.

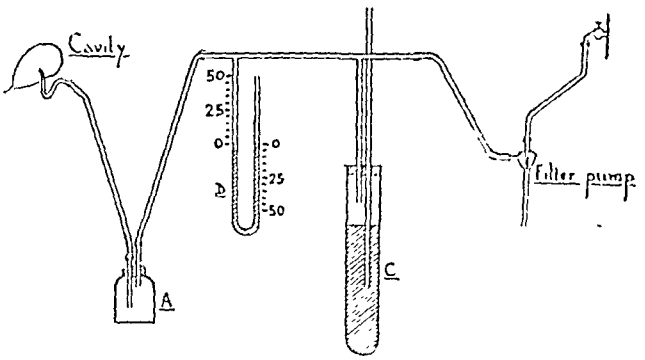

FIG. A.—Diagram showing method of drainage. A: Glass bottle which receives the matter aspirated from the cavity. B: Manometer graduated in c.cm. of water. C: Pressure controller (Jeanneret and Joyet, 1939).

During the first few days after the introduction of the drain a febrile reaction is generally observed. The matter aspirated, as also the sputum, is often blood-stained. It may be added, however, that often no trace of blood is seen.

The dressing must be changed daily, as strict asepsis is indispensable. The aspiration must be conducted very carefully and should be maintained night and day. It is usual to begin with a pressure of approximately −5. It must not be increased so long as the sputum or aspirated matter is coloured red. Once all signs of haemorrhage have ceased the pressure may be raised so as to reach −15 at the end of ten days. The degree of aspiration must depend on the clinical and radiological findings. If the suction is too intense the lung surrounding the cavity will tend to become opaque. This opacity would appear to be due to alveolar secretion, and diminishes when the aspiration is reduced. Care must be taken to avoid this complication, which could become very serious in cases in which the respiratory surface is already inadequate or in which the treatment is bilateral. The sputum, if it had its sole origin in the cavity treated, usually disappears almost at once. If not, it must be seen whether the drain is placed in its proper position in the cavity.

Frequent radiological examinations are necessary in order to carry out the treatment. At first the aspirated matter will be thick and the drain often become blocked. It may usually be cleared by means of a syringe. After the first few days the secretions become gradually more fluid, and finally all sediment tends to disappear. The suction may be increased gradually. The possibility of reaching a very negative pressure will depend on the permeability of the drainage bronchus. If the drainage bronchus closes a maximal pressure of −50 may be reached. In practice it would seem that the optimum figure is in the region of −20 to −30.

The decision to remove the drain requires careful consideration. It is not easy to decide whether the cavity has completely disappeared. Examination of the aspirated fluid will help in the decision. It will also be observed

that the drain may even hinder final disappearance of the cavity. When it is decided to withdraw the drain it is best to do so gradually.

Cases in which to apply Drainage

This method of drainage will be best applied to cases in which, as has been previously mentioned, the mechanical factor has predominated and in which there is peri-cavernous atelectasis. It may be employed to advantage in many cases in which the tissue surrounding the cavity appears to be fibrous. Its application in such cases has shown that there often remains a surprising possibility of retraction. In the case of some giant cavities, in which treatment by aspiration offers but slender hope of a complete result, drainage treatment can improve the patient's general condition and, by reducing the size of the cavity, render surgery more feasible.

In patients subject to frequent haemoptysis or in cases with marked dyspnoea the decision to apply the method must necessarily be a difficult one. A cavity of too small dimensions would make the introduction of the drain impossible. Cavities situated close to the hilus or to the mediastinum should generally be avoided, as their position renders the operation too dangerous. Provided that the details of the technique are carefully observed and that the respiratory balance is not too greatly compromised, the method may be applied to both lungs simultaneously. It may be added that in the case of a cavity with a free drainage bronchus a too rapid aspiration may lead to dyspnoea, sore throat, and dryness of the mouth. The dangers suggested by the puncture of the lung would appear to be attenuated by practice of the method. The risk of embolism is lessened by keeping the exploratory needle and syringe filled with fluid. Exploration by means of this needle will show whether there is an important vessel in the proposed course of the trocar and cannula. Haemorrhage would nevertheless appear to be the principal danger, and its possibility must be constantly borne in mind. The risk of a pleuro-pulmonary fistula is ruled out by making sure that the pleura is adherent. In practice the external fistula causes no trouble if the dressings are carried out often enough. This fistula tends to close round the drain rather than to increase in diameter.

It is as yet impossible to appreciate fully every aspect of Monaldi's method. The question of the complete and durable closure of the cavity can only be answered by fuller observation. That remarkable and rapid improvement may be obtained would appear to be certain. This result can render collapse treatment feasible, and therein would appear to be one of the chief indications for the use of this method.

Case Reports

Case 1.—Large cavity of right apex. Complete rest treatment extending over a period of sixteen months. A.P. impossible. Phrenic evulsion done without result. Surgical treatment impracticable. Fig. 1 on Plate shows size of cavity eight days before operation. Drain introduced July 12, 1939. Febrile reaction reaching 102° F.; temperature normal five days later. Aspirated matter slightly blood-stained during first three days. Immediate cessation of sputum. Fig. 2, taken December 6, 1939, shows that the cavity has almost completely disappeared. General condition now excellent; aspirated matter very fluid, and negative on repeated analysis; wound in good condition.

Case 2.—Giant cavity of upper third of left lung. Smaller cavity in right apex. A.P. impossible. Surgical treatment impracticable. Fig. 3 shows size of cavity seventeen days before operation. Drain introduced August 14, 1939. Slight febrile reaction lasting four days. Fig. 4 taken January 30, 1940: the cavity is still visible, but has greatly diminished in size; wound in good condition.

Case 3.—Giant cavity in upper portion of left lung. A.P. impossible. Surgical treatment impracticable. Drain introduced October 23, 1939. Febrile reaction reaching 103° F., lasting three days. Fig. 5 shows cavity eight days after drainage. There is a small cavity just below, and masked by, the cavity treated. Fig. 6, taken on January 30, 1940, shows that the cavity has almost disappeared: the smaller cavity, no longer masked, is more visible; and the wound is in good condition.

FEMINISM

BY

L. R. BROSTER, O.B.E., D.M., M.Ch., F.R.C.S.

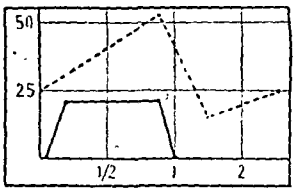
Surgeon, Charing Cross Hospital

(WITH SPECIAL PLATE)

In contrast to our series of cases of virilism in women which we have published at different times from Charing Cross Hospital we have for several years been observing the rarer and opposite condition of feminism in the male, a case of which is here described.

Case Report

The patient, who first presented himself in 1933, was so distressed about himself in 1939 that he threatened to take his life unless something was done. His plight may best be described in his own words:



> "Since the age of 13 I have never developed: my voice has not broken, I am physically still a small boy, and in the present state have not a man's strength and can never hope to get married, although I do get sexual feelings at periods. I cannot associate with men because they think I am a lad and address me as 'Son,' 'Lad,' or 'Boy'; neither can I associate with youths, as I have got past their stage of life mentally and they are in fact too full of life for me. I have tried many treatments, but to no avail, and I think I have to go through life as another Peter Pan, the boy who never grew up. I have never shaved yet, and am practically hair-free on the body. I am beginning to dread the thought of going through life as a bachelor. I have seen other boys grow up, get married, and have children, and I would like to be the same as they."

When seen in 1933 he was 32 years old. His family history was normal, and his brother was the champion boxer of the Southern Command. At the age of 12 he had had diphtheria, and says that he had also had what was called mumps when 12, and again at 13 and 14, but it did not involve the testes. He never developed normally at puberty, and at the age of 22 began to grow a few hairs; he has never shaved, his voice has not dropped, and when 23 he grew five inches in height.

Physically his bodily contour was then distinctly feminine; he was 5 ft. 5 in. in height, his weight 8 st. 5 lb., and his pelvic girdle (31 in.) wider than the pectoral (30 in.). His external genitalia were small—the penis was about 2 in. long, his testes were descended and about the size of hazel-nuts—and he had a few sparse pubic hairs. In his manner this young man gave the impression that he was still psychologically at the age just previous to puberty. His sexuality was more or less neuter; he had an occasional erection but never any emissions. His mentality was good, but his temperament somewhat unstable; he was self-conscious, timid, and nervous in the dark. He was a house-painter and decorator by trade, and was keen on swimming. Although his skin was smooth there was no breast enlargement or that sleek adiposity of the eunuchoid type which we have observed in cases of bilateral torsion of the testes at an early age, so that it appeared improbable that he had suffered from orchitis as a result of mumps.

In 1933 he was admitted to hospital, and investigations gave the following results:

A blood analysis showed: urea, 29 mg. per 100 c.cm.; cholesterol, 0.13%; phosphorus, 5.28 mg. per 100 c.cm.; calcium, 9.52 mg. per 100 c.cm. A radiograph of the pituitary fossa was normal. A fractional test meal gave the following result:

Uroselectan *x*-ray findings were normal, but there was a calcified mass below the right kidney.

A blood count showed: R.B.C. 4,880,000 per c.mm.; Hb. 94%; C.I., 0.9; W.B.C., 7,200 per c.mm.; polymorphonuclears 57.34%, large hyalines 6.00%, small and large lymphocytes 36.37%. Blood platelets amounted to 200,000 per c.mm., and the coagulation time was 4½ minutes.

The Aschheim-Zondek and Wassermann reactions were negative. The basal metabolic rate was 7%.

He had previously been treated with hormones for two years at another hospital, and we had decided that should a suitable patient present himself at hospital offering testicular grafts we should adopt this form of treatment. He then had injections of testosterone, and in 1934 bilateral testicular grafts were implanted in both his flanks at the Middlesex Hospital; early in 1939 he had "tablets" placed under the skin of his abdominal wall.

In May, 1939, he presented himself again at our hospital. His condition was *in statu quo*, and in view of his previous treatment we suggested that his adrenal cortex might be involved in the syndrome, and although we could make no promise of a satisfactory result he welcomed the idea of unilateral adrenalectomy, realizing that it was entirely in the nature of a test case. He was now readmitted into hospital. Laparotomy revealed that both adrenals were larger than normal. A fortnight later (June 16) the left adrenal was removed and the patient made a satisfactory recovery. The immediate result of operation was a chordee which lasted for a day and a half.

Histological examination by Dr. Vines showed that the cortical cells were normal, but that they gave the positive Ponceau-fuchsin reaction, but of moderate degree, which we have previously illustrated in the *British Journal of Surgery* (May, 1939) in association with different degrees of virilism in the female (Broster, 1939).

In addition we were also enabled, as a result of the Wakefield Research Fund, to carry out biochemical tests. Dr. Patterson's results from urinary analyses may be tabulated as follows (Broster and others, 1938):

	Pre-operative		Post-operative
	Mg. Sterone per diem		Mg. Sterone per diem
Sterone Colour Test:			
22/5/39	7.8	23/6/39	4.0
23/5/39	6.7	27/6/39	5.2
24/5/39	8.5	28/6/39	4.3
25/5/39	6.9	3/7/39	5.9
26/5/39	8.5	15/3/40	8.6
30/5/39	7.1		
31/5/39	8.8		
Average ..	7.7	Average ..	5.6
	I.U. per diem		I.U. per diem
Biological Capon Test: Collection 22-25/5/39	28	Collection 23-28/6/39	18
Oestrin: Collection 22-25/5/39	85	Collection 23-28/6/39	83

The normal control figures for the colour test in the male are 9 to 20 mg. sterone daily, and in the female 4 to 14.6 mg. daily; so it will be seen that the average figure in this case is definitely on the low side. We ourselves have not done nearly enough controls to establish the exact normal ranges for androgens as determined by the capon test, but, taking a line through other people's results obtained from fairly extensive investigations into the normal, it would appear that the normal male range is something like 20 to 100 units a day, and the normal female 10 to 50 units. The oestrin figures show that there was no excessive output and no appreciable alteration as a result of the operation.

Clinical After-results

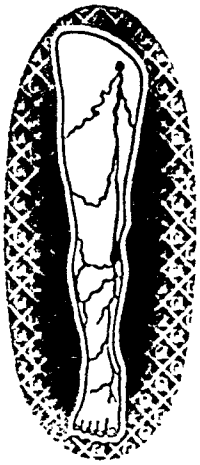
A letter received from the patient three weeks after the operation said: "I am certain there is already an alteration in my voice; hair has grown on my hands and on my arms, now an inch long." A month later he reported to the out-patient department; his voice had dropped, and he had shaved three times. It was not till January, 1940, that he reported again, looking much more manly and confident. He asserted that he had grown an inch since his operation, his appetite was enormous, and he had put on a stone in weight. The scrotal sacs were fuller and corrugated much in the same way as obtains after pregnyl injections. His penis had doubled in size; there had been erections but no emissions.

He was seen about the time of his operation and again in February, 1940, by my psychological colleague Dr. Clifford Allen, who reported:

"He has lost his shyness and will approach anyone without nervousness. He is more fidgety but less energetic at his work, and more keen to enjoy his pleasure. His moods fluctuate rather more than before his operation, but mainly concerning the possibility of a cure of his condition. There is no doubt that his operation has made a considerable difference in his personality. He is bolder, more self-reliant and self-assertive, and less secretive. He has attempted more sexually, and with success, than ever before, and is definitely more normally heterosexually inclined. Even his dreams and fantasies show this. The exact significance of his emotional shifting from his work to his pleasure is not yet clear."

Discussion

The detailed investigations of this case have been set forth in accordance with the routine which we had established for virilism in women. It came both as a surprise and a paradox that the opposite condition of feminism of the male should resemble the masculinization of the female so closely, both with regard to the presence of the Ponceau-fuchsin stain in the cells of the adrenal cortex and in the decrease in the amount of sterone after operation. It may be, as Vines suggests, that in all these cases of sexual disturbance of apparent adrenal origin there is an underlying dispituitarism which we have been unable to assess; but from a purely chemical point of view the findings might be harmonized with the theory, which has been advanced from time to time in regard to steroid metabolism, of the existence of a common precursor of androgenic, oestrogenic, and adreno-cortical hormones.



These comparative investigations are of considerable interest to the question of androgenic activity in both sexes from the adreno-cortical point of view, but although improvement has been maintained further progress does not seem likely after a year, and his age is against him. How far the adrenal cortex alone is responsible for the syndrome and whether secondary endocrine compensation takes place are matters for the future to decide.

Immunization against diphtheria of all children from 1 to 10 years and the use of Credé's method for the newborn have been made compulsory in the municipal institutions of Buenos Aires.

Sclerosing agent of 6 marked advantages

An aqueous solution of ethanolamine oleate (5% w/v), benzyl alcohol (2%), 6 x 2 cc. Bottles of 15 cc. and 30 cc.

Designed to bring a greatly increased measure of safety and certainty to the injection treatment of varicose veins, the Glaxo product Ethamolin has proved its effectiveness both in trials and in extensive practice.

Briefly the advantages of Ethamolin are that it ● gives a firm, adherent thrombus ● contains no impurities ● does not cause sloughing, even if leakage occurs ● does not cause muscular cramp on injection ● is constant in potency, which is retained indefinitely ● is available at extremely reasonable cost.

Ethamolin thus virtually eliminates the disadvantages which were formerly liable to attend vein treatment, and provides every practitioner with the means of undertaking the injections with confidence of safety and success.

INJECTION TREATMENT FOR VARICOSE VEINS

GLAXO LABORATORIES LTD., GREENFORD, MIDDLESEX BYRon 3434

MULTI-VITAMIN NOURISHMENT

The accentuated need for high vitamin protection is soundly met by a routine of Ostomalt. An agreeable, convenient and concentrated tonic food, Ostomalt provides the protective and formative elements of the four vitamins, A, B complex, C and D, with calcium glycerophosphate, combined in a highly nutritive malt base. Patients, especially children, readily accept Ostomalt for its attractive flavour, and may be interested in a homely comparison of thevitamin value of Ostomalt. Thus one teaspoonful of Ostomalt gives the vitamin A of two eggs; the vitamin C of a teaspoonful of orange juice; the vitamin D of 5 pints of summer milk; the vitamin B of two slices of brown bread; plus the energy value of a teaspoonful of fine malt.

As a prophylactic precaution, or as a routine in convalescence, Ostomalt is widely prescribed to restore and maintain a healthy robust condition.

A PROSTHETIC ULCER OF THE MOUTH

BY

H. T. SIMMONS, M.D., Ch.M., F.R.C.S.

Honorary Surgeon, Christie Hospital and Holt Radium Institute, Manchester

(WITH SPECIAL PLATE)

Benign tumours of the buccal cavity are uncommon. In two recent years 660 cases of disease of the mouth were examined at the Holt Radium Institute, and only 80 of them were non-malignant. Of these non-malignant cases 20 proved to be benign tumours and the remainder were inflammatory. Malignant growths therefore formed 97% of tumours in the buccal cavity, and 3% were innocent. These innocent tumours are important, however, because unless recognized they may receive unnecessarily drastic treatment, and if radiotherapy is used there will be little effect upon the growth.

One tumour, running true to type and possessing well-defined characteristics, has occurred often enough to merit description, especially as it has been invariably suspected of malignancy. Current surgical textbooks and literature do not mention this swelling, but a search through dental writings has revealed a description of a case by Thoma (1934).

The swelling lies in the sulcus between the cheek or lip and the gum, and is situated anteriorly to one or other side of the midline. It is much more common in the lower than in the upper jaw, and in women than in men. A series of ridges are formed which run parallel to the line of the alveolus and are slightly deeper in colour than the surrounding mucosa (Plate, Figs. 1 and 2). There are always two or more ridges, about an eighth of an inch in thickness and as much as a quarter of an inch in height, and after running for an inch or more along the gum they gradually slope away into the normal tissues. The ridges are covered with mucous membrane, but in the furrows ulceration exists in the deeper parts. On palpation the tumour is surprisingly hard, and this undoubtedly gives rise to the suspicion of malignancy. Very little movement on the deeper tissues can be detected because the swelling is anchored to the alveolus by the innermost furrow. There is little tenderness except during attacks of inflammation, which occur at infrequent intervals. It is only during these attacks that pain is experienced, and the main complaint is inconvenience, with a feeling that "this swelling ought to be attended to because it might lead to cancer." The patient is past middle life, and the gum is always edentulous. Advanced atrophy of the alveolus makes the denture very loose-fitting, and it will slip into any one of the furrows without inconvenience to the patient. The denture is an old one and has never been remodelled. The atrophy of the edentulous alveolus and the wearing of the loose-fitting denture are the cause of this variety of prosthetic ulcer, the "hit-or-miss" fit explaining the number of the ridges.

On microscopical examination the epithelial surface is irregular, but, although it extends fairly deeply into the underlying stroma, it is everywhere limited by a definite membrana propria. The underlying stroma shows scattered blood sinuses with occasional foci of lymphoid cells indicative of chronic inflammation.

The diagnosis from carcinoma is not difficult, but the patient usually presents himself when there is an acute attack of inflammation. The tumour is then reddened and angry-looking, with ulceration between the ridges. He has discarded his denture, and therefore the mechanical cause of the condition is not at once evident. The extreme hardness of the swelling and the induration of the base due to the ulceration in the furrows still further suggest the diagnosis of malignancy. On the other hand, the growth has been present many months—often one or two years. The hypertrophied portions are not friable, and bleeding does not occur. The ulceration is confined to the deepest portions of the furrows, and if the denture is obtained it will be found to fit accurately in any furrow. Finally there is no involvement of the regional lymphatic glands.

I have had 12 cases of this condition under my care in the past seven years, 9 of the patients being females and 3 males. Their ages ranged from 41 to 75 years, the mean being towards the end of the sixth decade. All were completely edentulous, and the original false teeth with which they had been supplied had been worn from five to twenty-six years. The atrophy of the alveoli was very advanced, the denture fitting loosely and slipping about whilst the patient was talking. Normally the lower denture in an edentulous mouth is much less secure than the upper, and this additional factor of instability would explain why in 10 cases the lower jaw was affected and in only 2 the upper. The tumours had been present from two months to five years, with the majority of patients seeking advice from six months to two years after noticing a swelling. In 2 cases the onset was painful owing to the pressure of the denture, but pain was infrequent and never severe. None of the patients suffered from gingivitis or stomatitis, nor was there any evidence of previous syphilitic infection.

The histories of the two cases illustrated are as follows:

Case 1.—A shopkeeper aged 62 had worn the same dentures for fifteen years. Two years before attending the hospital he developed a painful swelling "like a gumboil" on the inner aspect of the left lower lip. The swelling slowly increased in size, and was painless except when attacks of inflammation occurred. It had always been hard: there was no discharge and no bleeding. The patient was a teetotaller, did not smoke, and the Wassermann reaction was negative. On examination there was a typical prosthetic ulcer in the left lower alveolar sulcus 2.5 by 1.5 cm. in size (Plate, Figs. 1 and 2). The lower denture was very loose-fitting and slipped in and out of the furrows of the ulcer. There were no palpable lymphatic glands. The ulcer was excised with the diathermy loop and microscopical examination confirmed the clinical diagnosis. The wound healed in six weeks and the wearing of the remodelled dentures was resumed six months afterwards. It is now seven years since the operation, and there has been no recurrence.

Case 2.—A housewife aged 45 had had all her teeth extracted nine years previously and the dentures she then obtained had not been altered. Twelve months before coming to hospital she noticed a small hard painless swelling on the inner side of the left upper lip (Fig. 3). This swelling had doubled in size in the twelvemonth and was painless except when the teeth were pressed into it. There was no discharge or bleeding. She did not smoke or take any form of alcohol, and there was no suggestion of syphilis. On examination a typical prosthetic ulcer was found in the left upper alveolar sulcus 2.5 cm. in length. The upper denture was loose and slipped down whilst the patient was talking. There was no enlargement of the neighbouring lymphatic glands. The ulcer was removed by diathermy in November, 1934, and the wound healed in just over a month. Histological examination confirmed the clinical diagnosis and there has been no recurrence. New dentures were obtained and worn six months after operation.

The best treatment proved to be excision of the ridges with the diathermy loop, and the base of the tumour was very lightly coagulated with the diathermy button (evipan anaesthesia was used). Healing took place in about a month, with very little scarring, the only treatment

required after operation being bland mouth washes. All the patients were warned before operation that they would require a new denture or remodelling of the old one, and wearing of the teeth has been deferred until six months after the healing of the wound. One case had been previously treated elsewhere as malignant disease, and received an efficient implant of radium element giving a dosage of 6,000 r. It was interesting to find that the tumour had proved completely resistant, although a certain amount of troublesome necrosis had occurred in surrounding normal tissue.

Summary

A type of benign prosthetic ulcer of the mouth is described.

It is suggested that its relative frequency, trueness to type, and well-defined characteristics warrant its recognition as a definite clinical entity.

The causation, pathology, and treatment are discussed.

Clinical Memoranda

Irreducible Intussusception in a Baby, treated by Resection: Recovery

(WITH SPECIAL PLATE)

The problem of irreducible intussusception has evoked a variety of surgical methods, all more or less unsuccessful. In small children the mortality is very high. Perrin and Lindsay (1921) in a series of 400 consecutive cases of intussusception in the London Hospital give these mortality figures for irreducible cases: all cases treated by resection, 70%; cases under 3 years old treated by resection, 100%; cases treated by other methods, 100%. The conclusion one draws is that resection, though very unlikely to succeed, is the only method worth attempting. The following case was successfully treated by resection in Addenbrooke's Hospital in May, 1940.

CASE RECORD

The patient was a boy of 18 months, previously quite well apart from bronchitis. He was admitted with a history of abdominal pain, severe vomiting, and absolute constipation for four days in spite of enemas. Castor oil had been given at the onset. He had been passing small quantities of blood for two days. On admission he was dehydrated, the abdomen was distended, with a step-ladder pattern on it, and a mass could be felt in the right iliac fossa. The pulse was 160.

Operation was carried out under ether anaesthesia. An ileo-colic intussusception was found, beginning about twelve inches above the ileo-caecal valve and extending to the hepatic flexure. As only a few inches of this could be reduced and the part was gangrenous and was considered quite unviable the whole mass was resected between clamps. Anastomosis was done between the side wall of the ileum above the closed end and the open end of the colon a short distance below the hepatic flexure. The child's condition was not alarming at the end of this operation.

Intravenous saline and glucose were given continuously for six days, the child's leg being immobilized in plaster for this purpose. A nasal tube was passed and the stomach contents were removed. The fluid withdrawn was at first offensive and dark brown, and it remained so for three days. On the second day he passed an offensive dark-coloured stool. On the third day the abdomen was less distended and he had a mild attack of diarrhoea. On the fourth day he was taking half an ounce of fluid hourly by the mouth. Convalescence was complicated by a mild attack of measles, with bronchitis and otitis media, but he was in good health when he left the hospital four weeks after the operation.

Anterior and posterior views of the resected piece of bowel are shown in Figs. 1 and 2 of the Plate.

Multiple Foetal Abnormalities

(WITH SPECIAL PLATE)

In view of the unusual and extensive type of abnormalities in the case described, I consider that it merits record. Careful search in the literature through the good offices of the librarian of the B.M.A. has failed to reveal a similar case with such extensive deformity.

CASE REPORT

Mrs. ——, aged 33, has an only child of 4 years, who is apparently normal in every way. Since this child was born she has had a normal menstrual history, and used no contraceptives. She can recall no personal accident or untoward incident during the second pregnancy such as might give rise to a monster.

The confinement, at a maternity home, was a breech presentation with extended legs. No foetal heart sounds were heard. Under general anaesthesia a foot was brought down, the breech delivered, and the first abnormality displayed itself as a hernia of the liver covered by peritoneum through the abdominal wall (see Plate). There was a deficiency in the chest wall, involving the third, fourth, and fifth ribs, through which the heart and pericardial sac protruded. Finally careful delivery of the head showed a condition of hernia cerebri. The vertex of the foetal skull was absent and the free skull border appeared continuous and apparently fused with the amniotic membrane, which enclosed the brain substance. The brain was normal on section. Beyond this was the placenta, firmly attached. The face showed double harelip and cleft palate. The foetal skin was clean and intact and of normal appearance. The foetus showed no sign of life. There was at least fourteen to eighteen pints of liquor amnii.

Ante-natal care had shown a consistently normal urine and blood pressure, with breech presentation, but this was not interfered with.

I beg to thank Dr. Burn, medical officer of health, Barnsley, for the photograph and for his general interest in the case; also Dr. Rose.

Barnsley. A. B. SLACK, M.B., Ch.B.

A Case of Unilateral Twin Ectopic Pregnancy

(WITH SPECIAL PLATE)

Unilateral twin ectopic pregnancy is a comparatively rare condition. Falk and Blinick (1938), having reviewed the literature and described two cases of their own, state that 65 authentic cases had been reported. Anderson (1939) describes a case of his own.

CASE REPORT

A woman aged 24 was admitted to the North Riding Infirmary, Middlesbrough, on August 20, 1940, with the following history. She vomited in the morning and had pain in both sides of the lower abdomen which sometimes passed round to the back. This pain was severe and persistent, and on admission rose in the abdomen almost to the costal margin. There was a history of two months' amenorrhoea. She had had two children, the youngest being 18 months old.

On examination the patient was markedly exsanguinated, cold, and sweating, and the pulse was rapid and weak. There was a slight blood-stained discharge per vaginam. The diagnosis of a ruptured tubal pregnancy was made and the patient was taken to the theatre immediately. Under general anaesthesia the abdomen was opened and the diagnosis confirmed. The peritoneal cavity was filled with blood; the right Fallopian tube was ruptured and the bag of membranes was found intact. Right salpingectomy was performed. The ovaries and left Fallopian tube were normal. An autotransfusion of blood was carried out. When the unruptured sac was opened clear

liquor amnii escaped, and the condition was seen to be that of uniovular twin pregnancy (see Plate).

The patient made an uneventful recovery and was discharged from hospital twenty-two days after operation.

I am indebted to Mr. D. C. Dickson for permission to publish this case.

WILLIAM C. SMITH, M.B., Ch.B.,
House-surgeon, North Riding Infirmary, Middlesbrough.

Twin Pregnancy after the Menopause

The following case may merit record by reason of two unusual features—namely, the occurrence of conception after the menopause and the birth of twins when an *x*-ray photograph, taken about the eighth month of gestation, showed only one foetus.

CASE REPORT

A woman aged 41 had previously had three single pregnancies, her youngest child being 8 years old. Her mother had had three sets of twins and a sister one set, the latter being stillborn. The patient menstruated regularly up to the age of 38 and thereafter at increasingly infrequent intervals and with decreasing loss until about the middle of 1939, when the periods entirely ceased. About June, 1938, she began to have certain menopausal symptoms—e.g., hot flushes, slight vertiginous attacks—and believing herself to have outrun her period of productiveness relaxed the contraceptive measures she had employed since the birth of her last child.

The first intimation that she was pregnant occurred when she observed foetal movements; she reported for examination on March 15, 1940, and was considered to be between four and five months pregnant. Later, on account of undue abdominal enlargement and the multiplicity of foetal limbs, the possibility of a multiple pregnancy was entertained, although at no time could more than one foetal head be palpated. At about the eighth month an *x*-ray photograph clearly showed a single vertex presentation. On the strength of this the woman was informed to expect only one child, and made her plans accordingly.

At term abdominal distension was marked, but this seemed to be accounted for by a fair degree of polyhydramnios. Labour was short and easy. A few mild abdominal pains during the night were followed by one or two short decisive pains in the morning, and the expulsion, vertex first, of a living male child weighing 5¼ lb. No escape of waters was noticed previous to the birth of this child. A short umbilical cord was ligated, and the arrival of the placenta awaited. The uterus at this time was disproportionately large and very hard, and for the next half-hour the mother experienced moderately severe bearing-down pains, in spite of which the placenta failed to appear. The pains ceased more or less abruptly, and it was then found that there was a bag of membranes high in the vagina, with a foetal head above it. The membranes ruptured on slight pressure, releasing a large gush of waters. The pains immediately reappeared, and a living male of 5¼ lb. was expelled, vertex first, quickly followed by a uniovular placenta.

That conception can occur after the onset of climacteric amenorrhoea is an established medical fact, but in view of the popular belief that this symptom marks the end of reproductive life it would be interesting to know if there are any criteria which unquestionably denote that further production is impossible. If none exist it means that a woman who has planned the size of her family over many years may be faced with a perhaps unwelcome addition at a time when she is less fitted for the extra responsibility, or alternatively that she must carry contraception into her dotage.

With regard to the radiograph, I have eliminated any possibility of exchange of plates, and, in view of the presumed unimpeachableness of the *x*-ray plate in the diagnosis of multiple pregnancy I should be interested if any of your readers can offer an explanation.

I am indebted to Dr. A. I. Maclean of Newton-le-Willows for permission to publish this case, which I saw in his absence.

Reviews

CHARLES WATERTON

The Squire of Walton Hall. The Life of Charles Waterton. By Philip Gosse. (Pp. 324; 1 colour plate and 7 half-tone illustrations. 15s. net.) London, Toronto, Melbourne, and Sydney: Cassell and Co., Ltd. 1940.

The name of Charles Waterton is known to everyone who loves to read of travels in unknown countries. He wrote of his wanderings in South America, where he went as a young man to get curare, or wourali, the native arrow poison used in British Guiana, which he thought might be useful in the treatment of hydrophobia. The joys of travel became a part of himself, and during the remainder of his life he was rarely at home for any long period. The Rev. J. G. Wood and Sir Norman Moore have given accounts of him, but he had no connected biography until Dr. Philip Gosse wrote this excellent account of *The Squire of Walton Hall*. Born in 1782, he died in 1865. Waterton came of an old Yorkshire family and was endowed with a competence which enabled him to maintain his position as "the Squire." Dr. Gosse shows him as a man of many parts. A lover of birds and trees, he was the first to make the park round Walton Hall, his ancestral home, into a sanctuary for birds. He was a skilled taxidermist, a naturalist without much scientific knowledge, a Roman Catholic, adhering strictly to the old faith, and of a freakish humour. Had he been given the opportunity he might have done much to help in the advances made by his contemporaries Darwin, Wallace, and Huxley, but he was lacking in a scientific training. For medical men his methods are full of interest. Dr. Hobson, his physician, who practised at Leeds, records that he saw Waterton, then aged 77, scratch the back of his head with his right great toe. His toes indeed must have been prehensile, for to the end of his life he was active in climbing tall trees. During his early life in the South American forests he walked barefoot and does not appear to have felt pain or what to most people would have been extreme discomfort. He slept habitually on the floor of an attic at Walton Hall with a block of wood as a pillow and wrapped himself in a cape for covering. He ate but little and, on advice given to him when a young man by Sir Joseph Banks, he abstained from every form of alcohol. He suffered from repeated attacks of ague, for the relief of which he took Jesuits' bark, bled himself copiously and repeatedly, often with a blunt lancet, and purged himself with strong cathartics; yet in spite of it all he lived into his eighty-third year.

Dr. Philip Gosse has written an interesting book which will be read by different classes of readers—by some for the accounts of the travels, by others for the portrait of an unusual personality. The notes made by Sir Norman Moore, some of which were utilized in the *Dictionary of National Biography*, have been placed at the disposal of Dr. Gosse by Lady and Sir Alan Moore. Incidentally, it is stated in the volume that Sir Norman Moore came of Quaker stock. The Moore family is not Quaker, though Sir Norman's mother came of Quaker stock. There are reproductions of Waterton's portrait in the National Portrait Gallery and of Percy Fitzgerald's sketch, which is a caricature.

ONE HUNDRED YEARS OF A MENTAL HOSPITAL

The Chronicle of Crichton Royal. The Story of a Famous Mental Hospital during its First Century. By C. C. Easterbrook, M.A., M.D., F.R.C.P.Ed. (Pp. 675; 104 illustrations. 25s. net, postage 9d. extra.) Dumfries: Courier Press. 1940.

The famous mental hospital, Crichton Royal, Dumfries, was founded one hundred years ago on the initiative of Elizabeth Crichton, a contemporary of Elizabeth Fry and worthy to rank with her in the annals of philanthropy. Mrs. Crichton devoted to this purpose a bequest of about £100,000 of her late husband, Dr. James Crichton. The *Chronicle of Crichton Royal*, which Dr. Easterbrook, who was its physician-superintendent for thirty years, has most painstakingly compiled, is a worthy record of a great institution which was declared at its opening in 1839 to be the most perfect of its kind in Europe. From the first it exemplified the humane and rational treatment of the insane, of which Tuke at the Retreat in York and Pinel at the Bicêtre in Paris were pioneers. They had no more convinced disciple than William Alexander Francis Browne, first resident physician at Crichton and father of the late Sir James Crichton-Browne. Dr. Browne not only dispensed almost entirely with mechanical restraints but he was the first to introduce a system of occupations and amusements for patients. In 1843 the first theatrical performance ever given in an asylum—a farce in which all the characters were taken by patients—was staged at Crichton, and in the following year the first journal of prose and poetry contributed by asylum patients was published there. These facts are mentioned by Sir James Crichton-Browne in a foreword which he contributed to this volume just before his death.

Dr. Easterbrook unfolds the story of Crichton year by year, devoting to each year a separate chapter. The contents of each of these hundred short chapters are arranged in a uniform series of sections—the list of trustees, directors, and officers, statistics of patients, particulars of accommodation, innovations in treatment or nursing, clinical and laboratory investigations, commissioners' reports, and any new legislation affecting the treatment of the insane. A footnote of general history is appended to each chapter so as to give a background of contemporary events. Thus it is a book not to be read right through, but a work of reference to be consulted, as it were, either in vertical section for the happenings of a particular year or in horizontal section to trace any particular development. The author, as is natural, devotes a good deal of attention to the period of his own superintendency, 1908–37, during which time 8,500 patients were under treatment. The recovery rate was 37%, with very little difference between male and female. He notes that the recovery rate of the voluntary patients exceeded that of the certified by only 5%—a circumstance to be attributed, he says, to the increasing tendency of patients who would formerly have been certified to seek admission of their own accord. The cases received have been mostly in the middle period of life—from 30 to 60 years of age—and two-thirds of the recoveries have also taken place during that period. The total duration of the mental illness in two-fifths of the recovered cases was less than six months, and in another two-fifths it was between six months and two years.

This *Chronicle* is the product not only of great industry but of affection such as not every institution can command. It includes much small detail—the prowess of the Crichton team in the cricket field, for example, and the renovation of the asylum piggeries—and no pains have been taken to avoid repetition; but it is possible to gather from it a picture of the development of the treatment of mental disorder in Scotland during the last hundred years with a fullness which could not have been obtained in any other way. We are able to trace, from the point of view of one institution, the emergence of new ideas and their fructification and practical results. The well-produced illustrations add to the value of the book.

ST. THOMAS'S REPORTS

St. Thomas's Hospital Reports. Second series. Volume IV. Editors: Prof. O. L. V. S. De Wesselow, Mr. C. Max Page, assisted by Mr. N. R. Barrett, Dr. J. St. C. Elkington, and Dr. A. J. Wrigley. (Pp. 198.) London: St. Thomas's Hospital.

This latest volume in the second series of reports from St. Thomas's Hospital, like its predecessors, reflects recent work in various branches of medicine. Mr. J. S. Richardson first reviews the researches of the last ten or twelve years which have determined the chemical constitution of the male sex hormone. It has now been found that testosterone, the secretion of the interstitial cells of the testes under the influence of the anterior pituitary gonadotrophic hormone, influences some cases of prostatic hypertrophy and benefits some disorders of the breast. Careful selection of cases is, however, necessary. One of the most interesting phenomena in the study of the circulation is the change over from the foetal to extra-uterine life. Prof. Barnard describes the changes leading to the closure of the ductus arteriosus, and Dr. Nosworthy discusses the normal stimulation of breathing, the factors responsible for asphyxia neonatorum, and the principles of active treatment. Few institutions possess the necessary resources to operate an oxygen tent, but Dr. Forest Smith and Prof. McSwiney show that there are many methods of administering with ease and certainty fairly high concentrations of oxygen, which are of proved value in the treatment of shock, abdominal distension, and acute cardiac failure. Mr. Belsey discusses the pathology and treatment of empyema thoracis, and Dr. Griffiths the conditions of insulin resistance in thyrotoxicosis, relating this to altered metabolism of the liver; there appears to be a correlation between insulin resistance and defective synthesis of hippuric acid. Dr. Elkington's contribution on the pathology, clinical picture, and treatment of cerebral abscess is timely; the experiences gained by careful observation and considered judgment in civilian work will be valuable when applied to war injuries. Mr. Neilson points out that orbital inflammation is usually a sequence of nasal infection spreading to the ethmoidal cells and through the periosteum to the orbit; open operation is the method of choice. The administration of food and drink early with massive transfusion by continuous drip have not materially lessened the mortality from gastro-duodenal haemorrhage at St. Thomas's, and Dr. J. B. Harman urges surgical measures. He recognizes, however, the difficulties of diagnosing bleeding ulcer from a state of gastrostaxis, and the technical problems of anaesthesia and operative procedure. These cases are among the most difficult that are encountered in hospital; the degree of exhaustion of the patient when admitted may be so great as to preclude success. More hope for them is to be found in the early diagnosis, efficient treatment, and subsequent supervision of cases of chronic ulcer, which is the precursor of the pernicious type of recurrent haemorrhage. The element thorium is the parent of a series of radio-active products, among them thorium-X, a disintegration product having a half-decay period of

about three and a half days. Thorium-X is a source only of pure alpha-radiation and is manufactured in England. It is used in alcoholic solution, which can be standardized. Dr. Prosser Thomas, who has had personal experience of its use over a period of two years, discusses its application in the treatment of certain skin diseases. Its main value appears to be in superficial skin affections, and encouraging results in the treatment of naevus are reported. Finally, Dr. Vass contributes a useful summary of estimations by chemical and biological assay of the water-soluble vitamins in body fluids.

THE CHILD'S DISCOVERY OF DEATH

The Child's Discovery of Death: A Study in Child Psychology. By Sylvia Anthony, M.A. With an introduction by Prof. J. C. Flügel. (Pp. 231. 11s. 6d. net.) London: Kegan Paul, Trench, Trubner and Co., Ltd.

Mrs. Anthony, an experienced educational psychologist, has set out to elucidate the young child's reaction to death. This is an important line of inquiry because, owing to their own subsequently developed fears and inhibitions, adults indulge in a great deal of muddled thinking on the subject, and so handle children unwisely and in such a way as to implant and perpetuate their own mistaken attitudes. Mrs. Anthony has been brought up along psycho-analytic lines under the influence of Prof. Flügel, who writes a foreword for her and draws the customary parallels between children's fantasies, folk-lore, and traditional legend. To the prejudiced this approach may be repellent, but the more the whole subject is studied from an unbiased standpoint the more it must be realized that the main trouble is the difficulty in expressing in words the reactions of the infancy of both the race and the individual. The reason is that these reactions are *much more of the nature of feelings than of ideas, and if "words are given us to hide our feelings"* they certainly fail, except in the hands of a few poets, to convey to others an exact description of the non-verbalized attitudes to the fundamentals of experience, and this more particularly in the case of children. Three methods of approach are used: first, "home records" of five families of children taken by the parents; eleven children were so studied. The second—the story-completion test—and the third—special modifications of a well-known intelligence test—were applied in the course of the author's routine work. Case records and examples are given, and the conclusions reached are that:

1. There is little justification for the common parental practice of hiding death from children or of laying a special ban on "gruesome" folk-lore or fairy-tales, since death occurs readily in the fantasies of children, though of course some children develop special anxieties relating to death which require careful handling.

2. There is a tendency for the child to feel a sense of guilt whenever a member of the family dies. This may result in irrational aggressiveness or despondency. To overcome this the child should be allowed to work out his feeling towards the dead person without sentimentality and without shocked astonishment if he expresses hostility to the person who has died.

Many phobias and compulsions arise out of conflicts centred around the fear of death and a desire to rejoin the loved person in death—all very vague and unverbalized, of course, but still felt.

3. It is perfectly legitimate and healthy for a child later to reject fantasies and thoughts of death, but only after he has assimilated this idea or better feeling in respect of it into his consciousness, and this assimilation is necessary whether there has been an actual experience of death in the family or not.

Notes on Books

A second edition has now appeared of the Penguin special *Science in War*, which was the subject of a leading article in our issue of August 3, 1940 (p. 158). A new section under the heading of "Pills and Mixtures" reinforces what was said in an annotation in the *Journal* of December 21 (p. 875) on Rationalization of the British Drug Industry. "The unprogressive character," the writer in *Science in War* states, "of the network that can be called the British Pharmaceutical Industry stands out not only in the lack of major research developments, but also in the internecine competition with which different firms market the same substances bought in a manufactured or semi-manufactured form from a single source. To the utter confusion of the public, and often of doctors too, one drug may be sold by a dozen different firms, under a dozen different names." The writer goes on to point out that the pharmaceutical manufacturing potential in this country is much less than that of a small country like Switzerland, and refers to the high state of organization of the industry in Germany. He believes that the tide of events is pushing the medical services of the country into an organized National Medical Service; with this there must develop a rationalized pharmaceutical service. The British pharmaceutical industry owes a responsibility to itself and to the country to make its contribution to research and marketing in a way that is worthy of the Mother Country of the British Commonwealth of Nations.

We welcome the appearance of the twelfth edition of *Cushny's Pharmacology and Therapeutics*, which since 1926 has been edited by Profs. C. W. EDMUNDS and J. A. GUNN. The three years that have elapsed since the last edition have seen a very rapid advance in many important branches of pharmacology. These changes have called for an extensive revision of the text, but this work has been carried out very thoroughly. Sections dealing with the sulphonamide drugs, barbiturates, vitamins, and certain endocrines have been very largely rewritten. Ever since it first appeared in 1899 this textbook has been recognized as a leading authority on the mode of action of drugs, and the present edition maintains its past reputation. The publishers are J. and A. Churchill and the price is 30s.

Preparations and Appliances

CRYSTOFLAVINE BURN LOTION

Recent discussion on the treatment of burns has brought to prominence the value of the "triple-dye" treatment originated by Aldrich in 1933.[1] One of the drawbacks to tannic acid is its lack of antiseptic power, which is provided by the dyes in the triple-dye mixture, the dyes used being active against both Gram-positive and Gram-negative organisms. Messrs. Crookes Laboratories point out that in addition to their tannic acid jelly (which itself contains the triple-dye mixture incorporated with the tannic acid), they have had available for some time a triple-dye lotion, under the name of crystoflavine burn lotion, designed for the treatment of burns in cases where circumstances or personal preference make it undesirable to use tannic acid. This triple-dye mixture, consisting of brilliant green, gentian violet, and acriflavine, was used with satisfactory experimental results confirmed by clinical experience. Thus Devine[2] treated twenty-seven cases with this mixture, and confirmed its superiority in resisting infection of the burnt area, and also found the mixture to possess a distinct analgesic action. Crystoflavine burn lotion is dabbed or painted on the burn and allowed to dry. A second treatment is given after half an hour. Blisters should be snipped and dead skin removed. No dressing is applied.

out to them, and the laboratory class-rooms were on the second and third floors of the Institute. One of the infected students who had not taken a course had visited the classrooms on three occasions during the term, but had neither drunk water nor washed his hands. The animal-room attendant worked on the second floor; the plumber had installed an autoclave on the first floor, and had worked in the basement while connecting up the autoclave. The typist worked in an office on the first floor of the building, but paid a daily visit to the *Brucella* laboratory. The salesman called at the typist's office on December 13 just long enough to leave advertising matter, and a second time for a few minutes early in January. Altogether 349 students had taken out courses during the autumn term; an examination of 316 of them showed that in addition to the active cases already mentioned forty-four others had subclinical infections. Since milk could be excluded the possibilities suggested were contamination of the sewage system, of the water supply, or direct contact. No evidence that the sewage system was contaminated could be obtained, and only by exercising very considerable engineering ingenuity was it possible to produce siphonage of water coloured with fluorescein through the cold-water tap at the basement wash-room sink and into the main water line. To obtain back-siphonage it was necessary to shut off the water from the town main, and this had never been done. In addition, the laboratory animals—guinea-pigs and rabbits—which were given water daily from the laboratory supply, were entirely free from *Brucella* infections. The other possibility was direct contact with carriers, and in favour of this was the fact that the majority of both the clinical and subclinical cases were in three laboratory classes; but when subjected to a critical analysis the figures were insufficient to prove any such hypothesis. One possibility on which, however, no evidence is forthcoming is that the ventilating system in the Institute became contaminated and that *Brucella* passed through the various rooms as a result of forced draught. It is known that *Br. melitensis* can live for as long as six weeks in dust. *Brucella* infections in individual laboratory workers have, of course, been known for years, the source of the contamination being usually put down to splashes of infected material getting on to the laboratory bench. No such herd infection of human beings such as has occurred in Michigan has previously been recorded.

RENAL FUNCTION IN ACUTE DIFFUSE NEPHRITIS

Although the pathology of acute diffuse glomerulonephritis has been studied for many years, there is still some doubt about the earliest changes in the glomerular capillaries and the effect these changes have on the glomerular circulation and on filtration through the capsule. Shaw Dunn[1] has recently studied the histology of fifty-eight cases of acute diffuse nephritis collected over many years in which death occurred in an early stage. He concluded that the first recognizable change is a uniform patency of the capillaries in all the glomeruli. The diffuseness of the lesion is striking, every capillary in every tuft being affected. The tufts are enlarged, and this increase in size is soon accentuated by the remarkable increase in cellularity of the tufts which all pathologists describe in the acute stage. The intertubular capillaries and the tubules are little altered. Shaw Dunn argues that this uniform patency and dilatation of the glomerular capillaries can account for many of the clinical features of the disease. As is well known, in the normal kidney the glomeruli work in shifts, only a small number being in action at one time. In acute nephritis the circulation in each glomerulus is slowed and filtration is correspondingly less, but as all the glomeruli are now in action together the total filtrate may be as great as under normal conditions, so that non-threshold substances will be adequately removed and the blood urea or non-protein nitrogen may remain normal; but there will be increased opportunities for reabsorption, and the urine excreted will be scanty in quantity, the reabsorbed salt and water causing hydraemia, a rise in blood pressure, and increased transudation of fluid into the tissues. Thus the oliguria, oedema, and possibly the hypertension of acute nephritis can all be explained by the renal lesion, and Shaw Dunn shows how theories attempting to explain the oedema by extrarenal factors are all unsatisfactory. A small leakage of protein from the dilated capillaries will be concentrated in the tubules and explain the often abundant albuminuria. The same author[2] demonstrated a similar uniform patency of glomerular capillaries in subacute nephritis of the nephrotic type, and explained the oedema of that stage on the basis of excessive reabsorption from the tubules, though it is accentuated by the lowered plasma protein content which occurs in these more chronic cases. Platt[3] independently arrived at the same conclusion—that is, that renal oedema in the acute and subacute stages could be explained by the combination of slow filtration and the use of more glomeruli than normal, leading to increased reabsorption and therefore retention of salt and water by the kidney. His arguments were based on the work of Verney and Winton on glomerular pressure. Thus it seems that there is a gradual return to the older and simpler view that in nephritis the renal lesion is sufficient to account for the clinical symptoms without postulating unlikely conditions, such as generalized increase of permeability of capillaries, which have never been shown to exist.

CHANGES IN CALIBRE OF RETINAL VESSELS

Localized constrictions in the retinal arteries are readily observed ophthalmoscopically in cases of severe arterial hypertension. How often these constrictions should be attributed to organic deformity of the vessel wall and how often to vascular spasm is a problem which still presents difficulties. In some cases the arterial wall at the point of constriction appears opaque and thickened, but usually the vessel wall is not visible with the ophthalmoscope. The disappearance of a localized constriction is regarded as evidence that it was spastic in origin, and transitory constrictions are common in essential hypertension and especially in the hypertensive toxaemias of pregnancy. As spasm can be persistent, a continued narrowing of an artery, or part of it, is not conclusive evidence that the narrowing is organic in character. To the limited and confusing pathological observations bearing on this problem Laughlin, Thomas, and Friedenwald[4] have made a useful contribution by a correlated ophthalmoscopic and pathological study on a dog suffering from vascular hypertension induced by the Goldblatt technique (partial occlusion of the renal arteries). The animal showed definite renal hypertension and advanced changes in the retinal arteries. After careful ophthalmoscopic studies with photographs and drawings of the retina had been made, one of the eyes was enucleated and cut into serial sections, and on an extensive analysis of this material the authors conclude that ophthalmoscopically visible arterial constrictions may occur without organic changes in the vessel wall, and that the converse is also true. While the relation between

[4] *Johns Hopk. Hosp. Bull.*, 1940, **67**, 79.

experimental renal hypertension in dogs and essential hypertension in man has to be elucidated, this study emphasizes the impossibility of determining the character of a given arterial constriction in the retina by ophthalmoscopic inspection alone. Bearing on the question of variations in arterial lumen are the observations by Cusick, Benson, and Boothby[2] on the effect of anoxia and of high concentrations of oxygen on retinal vessels. Previous workers have noted that colour changes in the retina and even variations in the size of the normally present angioscotomata occur with changes in oxygen concentration. The present authors report that in anoxia at simulated altitudes of 18,000 to 21,000 feet there is a dilatation of the vessels varying between 10% and 20%, while with high concentrations of oxygen there is a narrowing in calibre ranging from 10.5% to 37.7%. As a rule the veins show greater changes than the arteries. The authors hold that the changes in the size of angioscotomata observed under these conditions are largely, if not exclusively, due to the alterations in the calibre of the vessels themselves. In view of the intimate relation of the retinal circulation to that of the brain, these observations have an obvious bearing on the physiological problems of flight at high altitudes.

MEASURING VENTILATION

In 1936 an advisory committee of the Royal College of Physicians commented on the paucity of information available on the ventilation of small rooms. In order to remedy the deficiency, Mr. C. G. Warner, Ph.D., measured[3] the rate of ventilation on 312 occasions in thirty-one rooms in a block of older flats, a block of modern flats, three villas, and a modern university building (presumably the London School of Tropical Medicine). His procedure was to liberate a quantity of coal-gas and measure the rate of its disappearance with a katharometer—a device which makes use of the difference in the electrical resistance of identical heated coils exposed to pure air and the room atmosphere respectively. Outside wind-speed is an important factor in ventilation, even in a closed room, and in this experiment a higher wind meant better ventilation even when air gratings were closed. Even when a room is quite closed there is considerable infiltration through the cracks round doors and windows. In the modern flats the windows fitted well but the leakage round the doors varied widely; when gratings or flues were open this variation made a noticeable difference to the rate of air change. A small amount of window opening greatly increased the natural ventilation. Distempered brick walls, however thick, let much air through, but wallpaper stops an appreciable amount of this, paint more, and hard gypsum plaster —as used in the modern university building—practically all of it. Rooms in old flats admitted more air than did those in new flats when ventilators were closed, and rooms in new flats more than did rooms in the university building with their hard plaster. The rooms in private houses had qualities comparable with those of the rooms in old flats. Temperature difference between inside and outside did not seem to affect the ventilation, but it was not great. The minimum healthy air supply per person is about 600 cu. ft. per hour. The single bedrooms in the modern flats barely admitted this with the ventilators open; the double bedrooms in the older flats only admitted two-thirds of it with the ventilators closed. Fireplaces proved efficient ventilators, but gas-fire flues did not. When flues were closed in all types of buildings ventilation was much below the admissible minimum. The use of flueless gas heaters in small flueless rooms with ventilators closed should, in Mr. Warner's opinion, be reconsidered.

COMPULSORY EVACUATION OF CHILDREN

The Minister of Health has made an Order providing for the compulsory evacuation from the Greater London evacuation areas of children who are found on medical examination to be "suffering in mind or body as a result of hostile attacks or are in such a state of health as to be likely so to suffer if they remain in the area." Local authorities may order a medical examination, which will be carried out by doctors appointed by them, of any child under 14 years who is thought to be suffering in this way, and may direct that the child shall be evacuated within a specified period, which will be not less than seven days. Parents or guardians will be served with a notice of the medical examination, and may, within seven days of the evacuation order, appeal against it to a Court of Summary Jurisdiction. If the child remains in, or returns to, the area the parent or guardian and any person bringing the child back or harbouring it will be guilty of an offence under the Defence Regulations. It will be a defence to such a charge, however, if the parent or guardian can prove that a child was in London without their knowledge or consent. A Regulation has also recently been issued providing for the medical examination of children found in shelters. The Ministry of Health circular announcing these powers states: "While the purpose is to ensure the evacuation of children who are suffering by being kept in London, it is not expected that local authorities will have to go to the length of issuing directions for removal except in a minority of cases." It is hoped that where evacuation is necessary parents or guardians may be persuaded to agree to it.

WAR STRAIN IN EVACUATED CHILDREN

The Ministry of Health is to be congratulated on its foresight in having established in one reception area at least, the county of Huntingdon, a child guidance officer to counter the serious mental strain imposed on children by separation from their home surroundings. It is to be hoped that this experimental service may be expanded and extended to other districts. It is clear from what was said at a recent meeting of the Tavistock Clinic (reported on p. 124) that war strain in children is a matter calling for urgent consideration and that the main source of the condition lies not in the bombed cities but in the reception areas. Wartime circumstances impose on children an abnormal strain—the break-up of normal family life, loss of environmental security, irregularity of education, divided loyalties, and, above all, the fear of impending disaster to their families or to themselves. All these factors contribute to bring about a tension that is at times not far short of breaking point. Mr. Malcolm MacDonald, the Minister of Health, is reported to have said at Bristol early this week that "one of the most remarkable things about the war" is that bombing has not affected the nerves of adults and children to anything like the extent that was feared. It is also remarkable that children who are evacuated appear to be undergoing a greater mental stress than those who remain in bombed areas. This becomes evident in such reactions as enuresis, anxiety, depression, and disorders of behaviour. Many factors probably enter into the causation of increased mental strain among these evacuated children, but the chief one appears to be the break-up of home life and all that that means. Much must obviously depend on the attitude of the foster-parents, and the sympathy and love they are prepared to extend to these additions to their families. The foster-parent, unless she is an exceptional person, will find it difficult to give help to just those children

most in need of it, while the child who has adapted itself to the changed circumstances will more readily become one of a new family. There is in this situation a very real danger that the seeds of neurosis will be sown in an increasing number of children, and apart from the immediate distress and disability arising from this, there is the wider question of what these children will go through later as adolescents and adults. It will be lamentable if the adults of the future will have cause to regret the mental disharmony thrust upon them in a laudable attempt to save their bodies. Evacuation of children from bombed cities is a policy which has the whole-hearted consent of everyone, but there is a danger that the authorities, satisfied with the achievement of one aim—the physical safety of the children—may fail to see the importance of preventing the mental risks that they run. There are a number of child guidance workers in the country at present engaged on a variety of tasks because opportunities for doing the work for which they are trained are not available. There are also many women psychiatrists who could be mobilized to deal with children showing signs of nervous strain in reception areas. Perhaps the most satisfactory solution would be the formation of mobile psychiatric units in counties or regions to which the evacuated children have been sent. It is to be hoped that the Ministry of Health will give a lead to local authorities to undertake one more duty in addition to the many others that have been thrust upon them by the abnormal conditions in which we live.

SYMPATHICOMIMETIC DRUGS IN THE TREATMENT OF PSYCHOSES

There has been much talk about disturbance in the vegetative nervous system in psychiatric patients, but very little of the evidence is exact or well established. Some see in vegetative disturbances merely an effect of the emotional state characteristic of the psychosis in question; others see a manifestation parallel with the mental symptoms of a common underlying disorder of the central nervous system; while others see a clue to the cause of the psychosis. The matter is totally undetermined, and it may be that all three relationships are involved. Much biochemical as well as systematic clinical work remains to be done in this field. Meanwhile sympathicomimetic drugs have to be used empirically, and it is all the more important to have controls. It is a pity that Sir William Gull's classical clinical experiment—the treatment of rheumatic fever with peppermint water—is not more widely remembered. Tietz,[1] in a paper on the action of ergotamine tartrate on aggressively disturbed psychotic patients, records favourable results obtained in a previously tested large series of 150 cases, and examines some of the physical changes accompanying the clinical improvement. He concludes that the alterations in blood pressure and pulse rate, blood sugar, blood calcium and phosphorus are so slight as to exclude the possibility that the ergotamine is effective because of its peripheral action. The clinical results, therefore, if they mean anything, indicate a central effect, and it is stimulating, although wildly speculative, to bring them into line with Bard's work on a "centre" for behaviour patterns of rage in animals with the thalamus cut at a certain level. Does the ergotamine act by picking out a mechanism released or dissociated at the thalamic level, and subduing it? The level of neurological release may have a biochemical counterpart, and this, too, needs elaboration, and points to a set of problems of neurological, biochemical, and ultimately, at a higher level, of psychiatric relationships that has hardly yet been touched. Such studies as Tietz's are suggestive rather than satisfying; but there is nothing like trying, and many of the best-known remedies in medicine, even those recently discovered, have been hit upon by "mere empiricism." The drug should, of course, be given by a route known to be effective by its action in other respects, and in varying dosage; it is also necessary to have controls. It is surprising that this method of pharmacological clinical experiment has not been more used as a means of investigation into the aetiology of the conditions to which the drugs are applied. In the meantime, there are already interesting antinomies to be resolved. Assuming that ergotamine really does quieten aggression, why does adrenaline with a supposedly opposite action control the excitement of catatonia, as some believe? It is possible, of course, in scientific zeal to forget that the first duty of a physician is to relieve suffering. Why, in this series, was the ergotamine discontinued when it had been symptomatically so successful?

A POLISH MEDICAL SCHOOL IN EDINBURGH

The University of Edinburgh has offered to the Polish Government facilities, which have been cordially accepted, for the establishment in Edinburgh of a Polish School of Medicine. It will be staffed by professors and teachers now serving with the Polish Army in this country, and by professors of the Edinburgh faculty of medicine in such basic subjects as may not be represented among the Polish professors. Discussions are in progress between representatives of the Polish Government and of the University of Edinburgh to settle details of the scheme. The University has gladly undertaken to provide accommodation and material to the utmost of its power, and the city authorities have informally indicated that they will co-operate in the provision of opportunities for clinical instruction. By establishing the nucleus of a Polish faculty of medicine in Edinburgh one of the most important branches of Polish learning—medical research and teaching—will be kept alive, and as little time as possible will be lost after the war in reorganizing active medical services and medical education in Poland.

THE HALF-YEARLY INDEXES

The usual half-yearly indexes to the *Journal* and to the *Supplement* are now ready. They will, however, not be issued with all copies of the *Journal*, but only to those readers who ask for them. Any member or subscriber who wishes to have one or both of the indexes can obtain what he wants, post free, by sending a postcard notifying his desire to the Accountant, British Medical Association House, Tavistock Square, W.C.1. Those wishing to receive the indexes regularly as published should intimate this.

We announce with much regret the death at Grayshott, Hindhead, in his ninetieth year, of Emeritus Professor Frank T. Paul, consulting surgeon to the Liverpool Royal Infirmary and formerly dean of the medical faculty of the university.

Sir Henry Head, M.D., F.R.S., who left estate valued at £144,588, bequeathed the greater part of this to the Royal Society, for the advancement in England of the science of medicine.

Reports of Societies

ACTIVE IMMUNIZATION: SOME PRESENT-DAY PROBLEMS

At a meeting of the Section of Therapeutics and Pharmacology of the Royal Society of Medicine on January 14 a discussion took place on some present-day problems in active immunization. Sir WILLIAM WILLCOX, who presided, said that in view of the possible pollution of water supplies due to burst mains, the blasting of dust into the bodies of those injured in air raids, and the congregation of large numbers of people in shelters, the civilian population was running considerable disease risks, and the importance of immunization was rendered all the greater.

Dr. H. J. PARISH said that it was necessary to consider which diseases could be dealt with effectively by preventive inoculation, and whether, in the case of diphtheria at least, some compulsory measure might not be necessary and urgent. Now was the time to institute a campaign, *without waiting for a major epidemic*; anticipation of the event was the keynote of good preventive medicine.

Diphtheria

Immunization against diphtheria was safe and effective when properly carried out, but unfortunately the bulk of the child population had not been reached. In 1939 Sir John Ledingham advocated compulsory measures, and the need was greater to-day, especially for the younger age groups. Could procedure be simplified to facilitate mass immunization? In the present emergency the Schick test might be reserved for selected groups and to control modified methods. Proper spacing of doses of prophylactics and periodic reinoculation would ensure a high level of immunity. It had always been his policy to advocate two doses of alum-precipitated toxoid—A.P.T.—separated by one month's interval, for children. Recently he had advised the medical officer of a large industrial concern with many young employees to use two widely spaced doses of T.A.F., a milder antigen which was usually given in three doses separated by periods of a fortnight; the medical officer was anxious to reduce the number of injections and reactions. *Representative groups might be Schick-tested* to control the modified method, but, if this was impracticable, criticism was answered when it was remembered that the important consideration was to give some protection to as many persons as possible. But in the desire to reduce the number of injections it was important to beware of so-called one-shot methods. To induce a high titre more than one stimulus was necessary, and the length of interval was more important than the size of dose. It had been shown with guinea-pigs that two doses of 0.1 c.cm. of A.P.T. given at an interval of four weeks produced much higher results than a single dose of 1.0 c.cm. Nasal immunization (for periodic restimulation) had made little headway in this country because it sometimes caused inconvenience from reactions; but it had possibilities, and purified toxoids might again be tried by this route. Indiscriminate swabbing was to be discouraged; high carrier rates were an indication for widespread diphtheria prophylaxis.

Enteric Fever and Tetanus

Damage to water mains and sewers and the improvisation of sanitary arrangements in shelters made the risk of serious epidemics of enteric fever very real. Mass immunization was desirable in many areas, although there was no justification for compulsion except for certain wholesale-food operatives and people who might be exposed to special risks. The Army doses of 0.5 and 1 c.cm. vaccine at an interval of seven to ten days were worked out for young men in good physical condition, and more attention might be paid in civilian practice to physical state and body weight. It was a good plan to give the inoculations late in the afternoon and, if possible, at the week-end. The conventional dose might be further reduced if an effective response could be demonstrated by available tests. After the primary course very small periodic doses (for example, 0.1 c.cm.) were worthy of trial. Vaccine could be given during an epidemic without increasing the chances of infection, as was mentioned by Colonel H. J. Bensted in his recent Harben Lectures.

A year ago much more importance would have been attached to tetanus prophylaxis, but the incidence of tetanus in this war has been negligible. Members of the Land Army, A.R.P. workers, and others might be immunized with toxoid, but mass immunization of the population was not advised. Anti-tetanic serum should be given early to all wounded persons. Two doses of toxoid spaced by six weeks were quite useful, giving good immunity; wider spacing gave better results, but was usually inconvenient administratively. Women gave significantly higher titres than men, and boys up to the age of 4 were twice as susceptible to tetanus as girls, suggesting that females had a greater inborn resistance to this infection (see Marvell and Parish, *British Medical Journal*, December 28, 1940, p. 891). A third dose of 1 c.cm. after a long interval—seven to nine months—often produced a dramatic rise in circulating antitoxin, and counteracted any tendency to waning immunity.

Other Infections

Dr. PARISH considered that this country might have to pay dearly for its failure to make vaccination against small-pox compulsory, and infection by virulent strains from the Continent might tax the resources of the public health services. Whooping-cough prophylaxis might be indicated for the individual; any measure which would reduce the ravages of this infection, even slightly, should not be ignored. The large number of injections usually recommended was a deterrent to mass immunization. Research into the possibility of fewer doses and wider spacing was indicated. For measles, methods of active immunization were not sufficiently advanced to be worthy of serious consideration in the present emergency. Scarlet fever was fairly mild, although active immunization of staffs of hospitals was important. The success of chemotherapy in cerebrospinal meningitis had removed the necessity for consideration of meningococcal vaccine. In dysentery (Shiga) presumably formol toxoid could be made available for human immunization, and research to this end was now in progress. Results obtained with coryza and mixed influenza bacterial vaccines were not very convincing, and experiments were now being made with influenza virus vaccines.

Combined immunization with diphtheria and tetanus toxoids and T.A.B. vaccine had been in vogue for some years in the French Army, but, taking reactions into account, one would hesitate to ask the British Army to submit to it. Diphtheria prophylactics sometimes caused reactions in older subjects, tetanus toxoid rarely, and T.A.B. frequently. It might be useful to combine T.A.F. and tetanus toxoid, also tetanus toxoid and T.A.B. vaccine. T.A.F. plus T.A.B. was probably contraindicated for adults on account of severe reactions. Diphtheria A.P.T. should not be mixed with tetanus toxoid as it might go into solution and become ineffective.

In conclusion, something should be said in warning to those who neglected the usual precautions of sterilization of syringes and needles and maintained they never had a case of sepsis. Many sore arms ascribed to the prophylactic were really due to bacterial infection. Published and private reports demonstrated the grave risk incurred if the instruments were not sterilized by heat. Far too many practitioners relied on alcohol as a disinfectant, although its unreliability was well known. One set of syringes and needles should be reserved solely for inoculations, and another complete set for the withdrawal of pathological fluids. A fresh sterile needle should be used for each injection. An intensive campaign was no excuse for slip-shod methods.

Combined Immunization

Dr. J. H. MACLEAN said that the diseases which he regarded as of primary importance from the point of view of active immunization were enteric fever, diphtheria, whooping-cough, influenza, and tetanus. None of these was a disease against which there was active chemotherapy, but there were efficient prophylactic agents for all of them. In considering combined immunization against various infections, it must be borne in mind that this measure was for the convenience of the practitioner and the patient, and the mixtures should be constructed to suit the particular group of population which it was intended

to immunize. If large-scale immunization of the general population was to be carried out, then for reasons of urgency or for convenience it must be determined what combinations of antigens were effective, so that the number of injections was reduced to a minimum—for example, how far was it possible to combine (*a*) various bacterial vaccines, (*b*) bacterial vaccines and toxoids, and (*c*) bacterial vaccines and virus vaccines so as to obtain the best response to each antigen? The best spacing of doses had also to be considered, as well as the great variation in individual response. Was this combination of antigens sound immunology, and how far should it be extended? It had been found that healthy people did respond to mixtures. Inoculations of vaccine containing thirty different types of pneumococci had been given, and although thirty types were not tested, those which were showed an adequate response. Ramon had been successful in human immunization with combined diphtheria and tetanus toxoids. Extension of this mixing of toxoids may throw too much strain on the immunity mechanism; work was proceeding on this matter, and information would soon be forthcoming. In combining a bacterial vaccine with a toxoid, not only did the mixture not impair the response to each type of antigen but there was definite proof that in some cases the combination would enhance the response to the toxoid. T.A.B. plus tetanus toxoid was suitable for an adult civil or military population. Maclean and Holt had shown that the response to tetanus toxoid in man was five times better if combined with T.A.B. vaccine than when the toxoid was used alone, and Culver Evans and Maclean had obtained full responses in children immunized with a combination of whooping-cough vaccine and diphtheria A.P.T. Very little had been done on the combination of a bacterial vaccine and a virus vaccine, but if an emergency arose and a decision had to be made to immunize against an epidemic of influenza he thought it would be reasonable to combine a vaccine of the influenza virus with a vaccine made from the catarrhal organisms which might be definitely associated with the epidemic.

Active immunization in the presence of an epidemic had been claimed by those who had had to deal with large epidemics abroad to have cut short the epidemic. The negative phase was a definite bogy, but an adjustment of the usual prophylactic dose might be required, the practice generally being to give half the dose, which worked very well. Slowly spreading epidemics might thus be successfully combated. The significance of the individual responses did not seem to be appreciated. In a recent experiment 10 % of persons were found to be poor reactors, but there was not sufficient experience to convert the individual response into terms of susceptibility to infection. It was a very important public health question whether poor responders should be given a special course of immunization. It was known that they were greatly benefited by increasing intervals between doses and by being given a mixture of toxoid and vaccine, and in children it might happen that they should be given another course in which the toxoid would be incorporated with an irritating vaccine such as T.A.B. or whooping-cough vaccine.

Questions and Discussion

Dr. R. A. O'BRIEN mentioned the real problem of the bad responder, saying that if he did not respond to one vaccine he would probably fail to do so to another. He had found failure to respond to diphtheria prophylactics in children who were members of the same family; some hereditary factor might be concerned. It was interesting that Dr. Maclean regarded the negative phase in active immunization as a definite bogy which could be disregarded. Dr. BROWN spoke of the part played by the polymorphonuclear cells in combating tissue infections. Prof. A. FLEMING remarked that it was easier for a bacteriologist to show how to protect against disease than for the public to be convinced that they should be protected. To the general public a needle prick was a serious business, and the inoculated person attributed to the injection all his other troubles for the next month. On the question of sterilization of syringes Dr. Parish had not mentioned the boiling-oil method, which was most convenient economically and practically. It had been used at St. Mary's for thirty years. Dr. C. H. ANDREWES, in speaking of immunization against influenza, regarding it as a mixed infection of virus and bacteria, suggested that it was a mistake to mix two vaccines both unknown, because this would delay the acquisition of knowledge as to whether either or both were any good. Dr. H. SCHITZE said that the civil population, unlike the Army, was not immunized against enteric fever. He thought that civil defence workers and those who dealt with damaged water mains should be protected. Dr W. M. CROFTON spoke on the need for great care in the sterilization of syringes and needles. Major A. E. FRANCIS said that prophylactic doses in an epidemic, if supplies were limited, might be quite small. It was better to give the maximum number of people some protection than to give a few individuals normal doses. Surgeon Commander RAINSFORD asked as to the keeping qualities of a mixture of T.A.B. and toxoid. Dr. NORAH SCHUSTER said that it was her practice to give massive doses of calcium lactate before injecting T.A.B.

Dr. PARISH, in reply, said that some experiments had been carried out with nasal immunization against diphtheria in which purified toxoid had been incorporated with an ointment base; some adults suffered no inconvenience and responded well, but others preferred any number of injections to a nasal administration, and showed no increase in circulating antitoxin. He thought further research was indicated. He had experimented with the boiling-oil method of sterilization of syringes intentionally infected with sporing cultures, and had found there was growth in practically every instance after its use. The use of separate syringes and needles for inoculations and for the withdrawal of pathological fluids was recommended, in which case boiling the former immediately before injections were made would be quite satisfactory. Autoclaving was the ideal method, but was not always practicable. Dr. MACLEAN, also speaking in reply, said that in respiratory infections something could be done by the use of a bacterial vaccine. In the presence of an epidemic the use of smaller doses if necessary was certainly to be recommended. With regard to the keeping qualities of T.A.B. and tetanus toxoid, he had been using these mixtures out of the same bottles for some months, and they were still quite satisfactory. So far as calcium lactate was concerned, he had discontinued its use when the issue of rejuvenated typhoid vaccine was made: it was preferable to inject a small preliminary dose of vaccine to lessen the local and general reaction.

Correspondence

Medical Planning Commission

SIR,—In view of the increasing and undisputed importance of psychotherapy in medicine, may I suggest that the Institute of Psycho-Analysis and the Tavistock Clinic be invited to send delegates to the B.M.A. Medical Planning Commission?

Since the planning of medicine is only one facet of the nation's post-war reconstruction, it might be considered prudent to broaden the character of the Commission by including an economist, an industrialist, a banker, a trade union leader, and an architect. James Barrie would have included a romanticist, and perhaps even a patient.—I am, etc.,

London, W.1, Jan. 18. S. L. SIMPSON.

SIR,—On reading through the list of names of the Medical Planning Commission I, for one, was surprised at its composition, "for the purpose of reconstruction and reorganization in the field of medicine in the great war era." I made a rough division, and find there are twenty-nine specialists, twenty-three town members, and one county member. I have no objection to any of these names, but there are many serious problems in the country which require serious consideration, and country practice is not the same as a town one. How many of the specialists have a working knowledge of country practice and institutions?

It is surprising that the B.M.A. Executive Committee had not considered this in their selection. I see they have the power to co-opt extra members. It is to be hoped they will give consideration to the country practitioners' representation. No scheme will be complete without serious consideration of the many problems in our country districts.—I am, etc.,

Bicester, Oxon., Jan. 8. J. HOLMES.

SIR,—Dr. Alfred Cox writes in his congratulatory letter (January 11, p. 61) that he is particularly interested in your announcement that the "vision and aspirations of the younger men and women will not be overlooked," a view which is shared by many of us older ones. Dr. Cox states also that "there is always a risk that the minds of the older men, particularly when habitually immersed in medical politics, will become polarized. It is not easy [Dr. Cox says] for such men to get away from the ideas and technique of our 'proposals for a National Medical Service.' But it must be done." Such a statement from a past secretary of the British Medical Association, with long experience of medical politics, carries great weight and must be regarded as a serious warning to us all.

With this in view may we be informed (1) of the average ages of those who compose the Commission; (2) whether such youthful bodies as the "Socialist Medical Association," the "United Hospitals Socialist Association," and others will be invited to express their formal views of the proposed organization of the medical service for the nation (as they have given this their earnest consideration in the past); and (3) whether all allied and auxiliary medical services that exist, together with the laity concerned, will be consulted by the Commission in its work?—I am, etc.,

Woking, Jan. 13. F. G. BUSHNELL.

SIR,—The Medical Planning Commission has been appointed. This is a pity, because having more or less elected itself and having become "first in the field" it is unlikely to be supplanted by any other more representative organization. The present Commission savours too much of London and the big cities, too much of highly placed medical legislators and more or less whole-time administrators, and far too little of men who actually do the medical work of the country and by their experience realize the failings of medical organizations in their own areas as they exist to-day.

One of the first and most important duties of a Medical Planning Commission is to unite the three separate bodies which are drifting further and further apart—general practice, hospital services, and public health administration. No medical planning can ever be really efficient until these bodies are organized to work together, and to work together amicably and in a way complementary to one another.

The real pity about the appointment of this Commission is that machinery exists throughout the country to form a body thoroughly representative of the various kinds of work of all areas, including both members and non-members of the B.M.A. or any other medical organization. I refer to the Local Medical War Committees. These committees represent every kind of medical work of relative local importance, and, what is more important, they are in touch with all the present-day problems. Surely a body could have been elected from these committees representative of the services already mentioned, and to this body one or two medical autocrats and bureaucrats could have been added—not for use, but to give colour—a matter which would weigh far more with those Government Departments with which they would at any time have to negotiate.—I am, etc.,

Reading, Jan. 17. STANLEY C. ALCOCK.

SIR,—In October of last year a Local Medical and Panel Committee had a short discussion on some literature issued by the Medical Practitioners Union, and as a result drafted a letter to the B.M.A. asking for information and guidance. A reply came back that further information would be had in about a fortnight, but nothing further was heard until the publication of the composition of the Commission. What is the composition of this Commission? In the list of some sixty-eight names there are those of many consultants, members of the Council of the B.M.A., and representatives of the various learned bodies. But what of the poor general practitioners, who must number about 80% of the medical men in harness? These are the men who will be expected to work any scheme, and yet I can only pick out six or eight names of men who appear to belong to this class, and some of these are rather doubtful.

In his letter (January 11, p. 61) Dr. Alfred Cox appears to have some misgiving that the Commission will fail in its object, or, as he puts it, become "polarized." I am quite sure that to many of us Dr. Cox's fear is a certainty, if the composition of the Commission remains as at present. One can visualize many lengthy sessions of brilliant speeches by men whose knowledge of the life and work of the average G.P. is in inverse ratio to their knowledge of medicine or surgery, and who are inclined to think in terms of guineas rather than shillings. Then would follow a wonderful scheme, which the Government of the time would probably turn down at once as unworkable, and after that, silence.

I notice that the Ministry is to be asked to appoint "observers." What would they do? Where are your financial experts? After all, any scheme of this nature depends upon finance. Surely a Commission of this kind should consist of a *limited* number of G.P.s, rural as well as urban, and representatives of all the various branches of medicine and surgery. What about the men who for the last twenty-seven years have run the National Health Insurance Act and made it the success that it is to-day? If a State service comes it will be based upon and include the present panel system. Good representation of this class of men would ensure the elimination of the worst features of that scheme.

If this letter reads as a reflection on the actions of the B.M.A., it must be remembered that to many of us the only positive action was the voluntary giving up of a portion of our panel capitation fee at the time of the slump, as a "patriotic gesture."—I am, etc.,

Worthing, Jan. 16. H. DUNDAS MCCALL.

Medicine in a Changing World

SIR,—The article by Sir John Orr (January 18, p. 73) has opened up problems of the first importance not only to medicine but also to the whole sociological and economic life of the country, and I should like, with great respect, to express my disagreement with the comments in your leading article (p. 91).

You do not deny Sir John's affirmations that "the medical profession contains within it experts on every subject that affects human welfare" and that "it is the only organized group of men competent to make a statement on human needs," but you criticize and emasculate them, deprecate what you call "contamination" by political partisanship and economic theorizing, and advise that the cobbler should stick to his last.

Clearly and self-evidently, if these propositions are true, it is not only expedient for the profession to take an active part in political and economic problems but it is its bounden duty to do so. Calling this political partisanship is merely evading a vital question. Politics has become now literally a matter of life and death to the individual, and it is certainly time that it was taken out of the hands of party organizers and placed on a scientific basis, to be studied and organized strictly by the scientific method. We don't speak of partisanship in considering medical and other scientific questions. Opinions on these subjects are regulated by the evidence for and against. Economics and politics can be no exception and should be in the hands of people trained to deal with problems on scientific lines.—I am, etc.,

London, W.1, Jan. 18. FREDERICK DILLON.

SIR,—The stately caveat administered in the third leader of your issue of January 18 (p. 91) will, it is hoped, come as a shock and a disappointment to many of your readers.

Sir John Boyd Orr suggests (p. 73) that the medical profession should make, as its contribution towards post-war reconstruction, an authoritative statement upon the reorganization of our social and economic system necessary to satisfy the health needs of the whole population. Your leader writer advises, on the contrary, that in a changing world "the cobbler must stick to his last" and that the profession should enunciate desiderata without concerning itself with their realization:

> "They murmured as they took their fees,
> There is no cure for this disease."

To justify this aloofness an extravagant compliment is paid to political movements. We are told that if a scientific contribution of the kind suggested were made we, as a profession, should become politically allied. I think this is to misread the suggestion. Political movements provide marching songs, and sometimes lullabies, but a determined public opinion and expert

advice are necessary to the building of roads. Who should advise us to how the road to national health should be built if not the medical profession?

For more than a quarter of a century the medical services of the country have been left in a state of arrested development largely because no satisfactory system has been evolved for payment for the medical care of the dependants of insured persons. Are we to wait through another quarter of a century for accepted standards regarding nutrition, housing, mental development, and fun and games to become actualities while others fail to discover how they are to be paid for?

Whether we like it or not, a point has been reached at which medicine must take into consideration and bend to its will the science of economics as it once, though not too willingly at first, absorbed and made triumphant use of the discoveries of Pasteur.

Please, please, Mr. Editor, take your head out of the sand, in a changing world, and give us another leading article—I am, etc.,

Potters Bar, Jan. 19. MAITLAND RADFORD

*** But why walk with one's head in the clouds?—ED. *B.M.J.*

Treatment of Carcinoma of the Cervix

SIR,—Sir Alfred Webb-Johnson, when discussing carcinoma of the cervix in his recent Bradshaw Lecture, tabulates (January 11, p. 40) certain published figures of mine giving the results I had attained by Wertheim's operation up to 1928. I have recorded such results from time to time over a period of many years, and have always divided my cases into two groups: (*a*) those in which the regional glands were free of carcinoma; and (*b*) those in which they were carcinomatous. This is a classification based on facts ascertained in the operating theatre and histological facts in the laboratory, whereas the radiological classification of the cases into four stages is merely founded on clinical opinion and has a wide margin of error.

I have repeatedly pointed out that no true comparison can be made between cases whose grouping is so differently arrived at. The radiological classification is founded solely on the extent to which, in the opinion of the examiner, the primary growth in the cervix has spread, but there exists no fixed relation between this and the state of the regional glands, for they may be carcinomatous when the cervical growth is still very small, and, conversely, may be free when the cervical growth is most extensive.

Judge, then, my dismay when I see 212 operation cases of mine in which the glands were not involved lumped together by Sir Alfred into Stage I of the radiological classification (a stage restricted to very early growths entirely within the cervix), and my cure rate set down as applying to that stage alone, whereas in fact the greater number of the cases would, on the state of the cervix, have been radiologically classified as belonging to Stage III.

My five-year cure rate for all the cases I have operated on stands at present between 40 and 43%, according to whether cases lost sight of or dying of other disease are or are not included in the calculation. This result has been pretty constant since I began to do the operation, varying a little one side or other of 40%, from year to year, as luck was for or against. It might be surmised that the lowered operative mortality would increase the percentage of cures, but it does so only slightly, because the saving in this respect has chiefly affected the more advanced cases, which, if the patients survive the operation, add to the number of recurrences later on.

Moreover, my results as regards cure are about the average, being much the same as those recorded by other surgeons who have published theirs, and, indeed, such similarity is to be expected seeing that the method of cure (the operation) does not materially differ in different expert hands.

It is ill arguing from exceptions, and the main radiological figures which Sir Alfred quotes are incomparably better than the average results of radiation therapy as carried out by other institutions in this country under the direction of experts of established reputation, of which that at the Middlesex Hospital, in the charge of my most clever and conscientious colleague Mr. Windeyer, may be taken as an example.

Whether it is best to treat a case of carcinoma of the cervix by operation or by radiation (presuming the proper performance of either is at command) is a question whose answer needs much more knowledge and consideration than Sir Alfred has given to it.—I am, etc.,

Hereford, Jan. 13 VICTOR BONNEY.

Pride and Prejudice in the Treatment of Cancer

SIR,—Sir Alfred Webb-Johnson in his Bradshaw Lecture calls attention to the urgent need for radiotherapists to implement the provisions of the Cancer Act. Having been for many years examiner and lecturer for the Cambridge D.M.R.E. I have long foreseen that this difficulty would arise. During the four years ending 1938 the total intake of medical students in this country was about 10,000. During the same period the number who took the Cambridge diploma was 87. Of these, 29 were from over-seas, leaving 58—a yearly average of 14.5—from the British Isles. To these must be added the still smaller number who have taken the diplomas of other bodies, but from the total must be deducted the great majority who prefer x-ray diagnosis to therapy. These figures show that under present conditions there is not the smallest hope of providing the "great army of workers" which Sir Alfred considers essential.

There being no lack of facilities for instruction, the cause of this deplorable state of affairs clearly lies in the unattractiveness of conditions and prospects. The following, based on discussion with a number of experienced radiologists, appear to be the main reasons.

1. No one will deny that the advent of radiology in its twofold purpose has been one of the few great revolutions in medicine. In spite of this radiology has acquired in this country no academic status. It has no College of its own. Of university chairs there are none; of lectureships only one or two. In this respect we are lamentably behind all other great countries.

2. Many of the patients whom the radiotherapist sees come to him too late, either through their own neglect or through the failure of operative measures. His work lies largely among those whom the surgeon has discarded. However interesting it may be, it must have a depressing effect on those who practise it unless they are possessed of a sanguine temperament.

3. It is found that patients of moderate means can often afford fees for a surgical operation, but afterwards, when radiotherapy is found necessary, their means are exhausted and they become hospital patients.

4. Sir Alfred's liberal views on the proper status of the radiotherapist are not by any means universally shared. The attitude which is all too common was typified by a recent speaker at the Royal Society of Medicine who described radiotherapy as the "handmaiden of surgery"! It is the general experience that when a surgeon sees a patient and finds that he cannot operate, or that an operation which he has previously performed has been unsuccessful, he advises the patient to have *x*-ray treatment. When the patient reaches the radiotherapist the latter's course of action has virtually been decided for him. He may know better than the surgeon that the patient has reached the stage when *x*-ray therapy can do him more harm than good. But the surgeon's opinion has impressed itself so strongly upon the patient and his relations that it is very difficult for the radiotherapist to express a contrary opinion without running the risk of being thought disobliging. Late cases are frequently referred for *x*-ray treatment "so that the patient may feel that something is being done." Is the radiotherapist to give treatment against his judgment, or is he to deceive the patient by putting him under the tube without switching the current on? Why should not the surgeon perform a dummy operation? A course of *x*-ray therapy is the equivalent of a surgical operation. It has a definite curative or palliative object, and should not be carried out for any other purpose. As I have said elsewhere, the *x*-ray department is still regarded as the ante-room to the post-mortem room.

The greatest need at the moment is a fundamental change in attitude towards radiotherapy. Sir Alfred's dream will not materialize until pride and prejudice give place to sense and sensibility.—I am, etc.,

Cambridge, Jan. 17. FF. ROBERTS.

Effort Syndrome

SIR,—The two cases quoted by Dr. Middlemiss (*Journal*, December 28, p. 915) as examples of effort syndrome read so like cases of masked thyrotoxicosis that, as one who, having operated upon a number of such cases, has been impressed by the gratifying results of partial thyroidectomy, I feel constrained to raise the possibility. The "full" thyroid, tachycardia, and tremors of Case I, constituting three of the cardinal signs of Graves's disease, and the shortness of breath, tachycardia, and attacks of palpitation which followed an acute emotional disturbance (sudden death) in Case II are at least suggestive. These remarks are manifestly open to the criticism that I have not seen the cases quoted, but my object in making them is to draw attention to the importance of not overlooking masked thyrotoxicosis.

For determining the presence of this condition I have found the following three lines of investigation valuable: (1) Is the condition better in cold weather than in hot, and has the patient a good appetite in spite of the disturbances complained of? (2) What is the reaction to the adrenaline test? (Details of this have been previously and elsewhere recorded.) (3) What is the effect of small doses of iodine given over some weeks?

If the answers to these questions indicate a thyroid origin for the symptoms a good result can be predicted from thyroidectomy, and such patients may not only be rendered fit for general service but protected from a long period of invalidism.—I am, etc.,

Dec. 30. LAMBERT ROGERS.

Treatment of Bronchopneumonia in Infants

SIR,—Dr. A. Morton Gill's article (December 28, p. 900) was both interesting and of immediate clinical importance at a time of the year when an increasing number of cases of respiratory tract infection are occurring. I would, however, like to pass some comment on it, based on my personal hospital experience, because I feel that an increase in the dosage of sulphapyridine above the doses recommended by Dr. Morton Gill will result in a reduced mortality rate.

From November, 1938, to May, 1939, I collected a series of 160 consecutive cases of pneumonia to study the effect of treatment with sulphapyridine, and case papers for previous years were most carefully scrutinized to obtain comparable figures for cases treated without chemotherapy. From the figures then obtained I have now taken the cases of bronchopneumonia under the age of 1 year to compare them with the results published in your article.

Series	Cases	Deaths	Mortality
Dr. Morton Gill	11	4	36%
1937–8 (before chemotherapy) ..	17	8	47%
1938–9..	18	3	17%

My two series of cases are quite unselected. They include all patients with bronchopneumonia under 1 year of age that came for treatment from November to May in the years under discussion. In my cases from 1938 to 1939 I believe the relatively low mortality to be due to adequate chemotherapy. I did not use oxygen tents as a routine, and indeed I am of the opinion that the omission of oxygen with an easy mind is one of the advantages of treating pneumonia with sulphapyridine. The general nursing and feeding of my cases were much the same as Dr. Morton Gill's. The one essential difference was in the use of very much larger doses of sulphapyridine. The following four cases illustrate the doses employed.

(1) An infant, 19 days old, admitted on the third day of illness, had 1/2 gramme four-hourly for three doses, then 1/4 gramme six-hourly for three days.

(2) An infant 4 months old was given 1/2 gramme four-hourly for four doses, and 1/2 gramme eight-hourly for three days.

(3) An infant 3 months old, desperately ill on admission, was given 1 gramme, then 1/2 gramme four-hourly for four doses and 1/2 gramme eight-hourly for three days.

(4) An infant 9 months old had 1/2 gramme four-hourly for six doses and eight-hourly for three days. This infant was readmitted six weeks later with lobar pneumonia, and recovered after receiving 1 gramme on admission, 1/2 gramme four-hourly for six doses, and eight-hourly for three days.

It may well be that if the fatal cases in Dr. Morton Gill's series had received doses of this order for the first day of therapy the outcome would have been satisfactory. I believe that it is essential to give bigger doses early, and that it is then permissible to reduce both the dose and the frequency of administration. Thus Case 4 quoted above had 3 grammes in the first twenty-four hours, and a total of 7½ grammes, whereas Dr. Morton Gill's Case 7 had only 1¾ grammes in the first day. It seems to me certain that it is useless to endeavour to make up the total later in the course of treatment. This is the generally recorded idea in most chemotherapy, and it is well known that there is a risk of producing a drug-resistant infection by giving inadequate quantities at the start of treatment. I have never had cause to regret the administration of large doses to the smallest infants, and have given 1-gramme doses to an infant of 1 year with no ill effect on many occasions.

In treating lobar pneumonia in adults I have adopted the same type of changing dose. Since November, 1938, my adult cases have received an initial dose of 2 grammes, then 1 gramme four-hourly for four doses, and eight-hourly for three days. In the first eighty-four cases between the ages of 5 and 70 it was necessary to modify this course of treatment in ten cases only, and there were five fatal cases. It would be of considerable value to learn what doses other clinicians are using, both for infants and for adults.

I must thank the Medical Officer of Health for London for permission to publish these figures. He is in no way responsible for the views expressed in this letter.—I am, etc.,

London, S.E.10, Jan. 6. ALEXANDER KAHAN.

Malaria among Merchant Seamen

SIR,—In an interesting clinical memorandum (January 4, p. 14) on a case of malignant tertian malaria Drs. J. Fawcitt and A. H. Walters mention that there have recently been a number of deaths from this disease in several dockside hospitals. As there is reason to believe that in the immediate future there will be an increasing number of merchant seamen returning to this country at short intervals after calling at a malaria-infested port, the necessity for being on the look-out for this disease should be borne in mind by those doctors who may be called upon to treat merchant seamen in their homes and elsewhere.

This was brought home to me by a recent experience. A few weeks ago I was asked to go out to a troopship and examine some sick members of the crew. In the ship's hospital I found ten seamen who had been ill for about a week. Their illness had been diagnosed as gastric influenza. One man had died that day, and three were dangerously ill. All had more or less high temperatures, and vomiting was present in nearly every case. I found that the ship had called at a certain African port on the way home, and this suggested that malaria might be the right diagnosis in at least some of the cases. Owing to a shortage of the necessary materials I was unable to examine the blood of all the sick cases, but I was able to make films of the three worst ones, and had no difficulty in finding the rings of malignant tertian malaria. These three were immediately given injections of quinine. One of them died about twelve hours later without showing any response. A sample of his blood after death still showed a very heavy infection with rings. The two others remained dangerously ill for about twenty-four hours after receiving three injections each, then began to improve rapidly. The change in their condition when I visited them a few days later was most impressive. The rest of the patients were given quinine by the mouth and all made an uneventful recovery.

The danger of missing the diagnosis is increased when a seaman arrives in a home port feeling ill but unwilling to give up his home leave. He may then consult a doctor who is unaware that he is a seaman or has been recently in a malaria-infested port.—I am, etc.,

Paisley, Jan. 12. A. GARDNER.

Specific therapy
with

OESTROFORM *and* PROGESTIN B.D.H.

Oestroform is a natural form of the œstrogenic hormone of the ovary. Progestin B.D.H. is the hormone of the corpus luteum. The administration of Oestroform to a patient suffering from defective ovarian function is thus able to bring about all the characteristic effects produced by the natural secretion of the follicular hormone of the ovary, while a specific response is obtained with Progestin B.D.H. in all conditions due to hypoactivity of the corpus luteum.

OESTROFORM is specifically indicated in

Menopausal disturbances, both natural and artificial

Functional nervous disorders associated with the climacteric

Delayed puberty and failure of secondary characteristics to mature, under-development of the breasts, amenorrhœa and oligomenorrhœa

Hypoplastic conditions of the female reproductive system, sterility and dysmenorrhœa due to uterine hypoplasia

Disorders of the vulva and vagina, pruritus vulvæ, vulvo-vaginitis in children, vaginal hypoplasia and senile vaginitis

Conditions associated with pregnancy, vomiting of pregnancy, missed abortion, induction of labour, uterine inertia and inhibition of lactation

PROGESTIN B.D.H. is specifically indicated for

The production of a normal secretory endometrial phase in menorrhagia and metrorrhagia

The maintenance of pregnancy in threatened and habitual abortion

The relief of conditions due to abnormal uterine motility, dysmenorrhœa, after-pains following child-birth and tonic uterine contraction

The successful treatment of

FIBROSITIS AND CERTAIN CASES OF RHEUMATISM

with

NOVUTOX INJECTIONS

A mass of evidence has accumulated to show that the treatment of Fibrositis and certain cases of Rheumatism with Novutox injections provides restoration of function with immediate relief from pain, and in the majority of cases, an early recovery.

Novutox, which is a self-sterilising local anaesthetic, is prepared by a special process, and the preparation contains, in extreme dilution, certain highly complex quinine derivatives. Due to treatment by this process, Novutox solutions have a remarkable chemo-therapeutic action and also unique antiseptic properties which, associated with extremely low toxicity, are held to account for the very satisfactory results achieved with the preparation in the treatment of Fibrositis and certain cases of Rheumatism.

In an article entitled "Muscular Rheumatism—Local Injection Treatment as a Means of Rapid Restoration of Function," published in the "British Medical Journal," 10.8.40, page 183, the author describes the treatment of a number of typical cases of Fibrositis, etc., in different parts of the body and *in all cases* immediate relief was obtained following injections of Novutox. During an attack of lumbago suffered by himself the author found one injection abolished intense pain and restored function within a matter of minutes. He also gives useful detailed information of the technique employed for the various sites of the body.

Interested members of the medical profession are invited to write for a copy of "Notes on the Treatment of Fibrositis and Recent Injuries."

NOVUTOX is available in:
2 c.c. and 5 c.c. AMPOULES. 2-oz. BOTTLES and CARTRIDGES (standard size).

Manufactured by:

PHARMACEUTICAL MANUFACTURING CO., LTD.,

Sterilization of Dressings and Post-operative Tetanus

SIR,—The recent paper by Lieut.-Colonel S. N. Hayes on imperfect sterilization as a probable cause of post-operative tetanus (December 14, 1940, p. 825) raises a point of great interest and importance, especially at the present time.

A number of years ago a careful study of the conditions underlying efficient sterilization was made at the Jessop Hospital for Women, Sheffield, and an outline of the results obtained—which were in close agreement with those of Colonel Hayes—was published at the time (*British Medical Journal*, June 20, 1925). The outstanding importance of a really loose packing of dressings in the drums used as containers was clearly demonstrated there. The technique of sterilization adopted in this hospital since that time has been based on the results of these studies, and, as the details have been developed by further trials in the last few years, it may be of interest to state the precautions that are now adopted here with a sterilizing plant using steam from the hospital boilers.

1. The sterilizer is fitted with an automatic pressure and vacuum recorder which produces a written chart of the operations. These charts provide a check on the handling of the sterilizing plant and are kept as records.

2. At the beginning of the sterilizing process air is evacuated so far as possible and steam is then admitted to full (20 lb.) pressure for two or three minutes. Steam is then shut off and the sterilizer is re-evacuated, after which steam is again admitted and a pressure of 20 lb. maintained for twenty minutes or more. The object of the double evacuation is to replace the air contained in the dressings by steam more effectively. Numerous trials have shown that complete removal of air is not obtained by the first admission of steam, and this re-evacuation followed by the readmission of steam at the same pressure for twenty minutes or more has shown that the penetration of the steam is much enhanced by this manœuvre.

3. However carefully the sterilizing plant is operated, defective sterilization may still ensue if the goods have been packed too tightly in the drums or if the holes in the drums have not been opened. An internal check is therefore always employed by including in the centre of each drum a control tube (the Browne sterilizer control tube—a development of the control described in the 1925 studies) which changes colour as sterilization proceeds. The timing of the colour change has been adjusted to leave a wide margin over the thermal death points of tetanus spores as determined in the studies of Murray and Headlee (*J. infect. Dis.*, 1931, **48**, 436). The colour of the control tube is inspected when the drum is unpacked in the theatre and doubtful batches are unhesitatingly rejected.

By these means it is hoped to ensure that no batch of dressings will be used that is not certainly sterile.

The use of the control tubes, with their positive evidence of the application of steam for an adequate time, can always be retained, even under the simplest conditions, where the full technique is not possible.

To summarize—the use of the recording apparatus to check the work of the technician or nurse responsible for the sterilizing and to give him/her confidence in the manipulations, the employment of double evacuation to ensure rapid and adequate penetration of the steam throughout the materials, the loose packing of these, and the consistent use of the control tube as the final check accessible to the surgeon himself, provide a security which is well worth a little trouble and expense to attain.—I am, etc.,

Sheffield, Jan. 11. JOHN CHISHOLM.

Treatment of Scabies

SIR,—It may be of interest to those who may have to treat this troublesome complaint, especially in communities and institutions, to hear of my experience.

About the middle of the last war I was the only A.M.O. in a large mental hospital. We were very overcrowded, having had some drafts of patients in from other hospitals, and the nursing staff was depleted. During the early warm weather of one summer I detected some cases of scabies in a female ward of about sixty chronic and turbulent cases, the worst possible type to co-operate in any treatment, many of them being actively obstructive. The usual treatment—sulphur ointment and baths—was given, but fresh cases kept recurring. I also tried Vlemingkx's lotion, but this seemed to cause eczema in some cases.

I was getting rather desperate, but on reasoning from the fact that sulphur taken internally will cause silver articles and coins carried on the body to turn black, and that this is due to H_2S exuded from sulphur in the skin, and that fighting on internal lines of communication was just as topical then as it is now, I gave every patient in the ward a teaspoonful of confection of sulphur every day. The result exceeded my expectations. Within three or four days there were no more fresh cases, and within about ten days the ward was clear.

The patients took their confection willingly—maybe they had some unconscious urge to take it. The only complaint came from the nurses, who said the ward stank like a gasworks, and they were not much comforted when I pointed out that a gasworks was a very healthy place to live around, but they all worked very well and loyally.

Perhaps those people of past generations who used to dose themselves and their families with brimstone and treacle had more ideas in their method than the warding off of spring vapours and cleansing the blood. I cannot be dogmatic about this internal line of treatment as the external procedures were used with it; the time was not opportune for experimenting with controls, but in my own mind I have no doubt about the efficacy of it.

I do not know if this method of treatment is original, but I do say that I have never heard or read about it in any ordinary textbook; perhaps I have not delved deep enough into the subject.—I am, etc.,

Croydon, Jan. 14. H. M. BERNCASTLE.

Recurrent Attacks of Herpes

SIR,—The following case seems to be worthy of publication because of the rarity of such a condition and the apparent lack of any cause.

The patient, an ordinary seaman aged 22, suffers from recurring attacks of herpes of the left auricle. These occur every October without fail and the course is always the same. First blisters are noticed; then slight pain develops in the upper part of the sterno-mastoid muscle: finally both pain and blisters disappear after about two weeks. It is never complicated by sepsis; it never occurs except in October; it has happened as long as the patient can remember.

On examination the patient seems to be a perfectly ordinary individual of good physique, and with no detectable nervous lesions or other possible conditions which might account for the herpes. I got the impression, while taking the history, that the patient was truthful, and his story has remained consistent in spite of trap questions. The only explanation I can offer is that the condition is psychological in origin, but I have not had the necessary experience to investigate properly this side of the question. It is interesting to note that his birthday is in October. There is a history of mumps and measles as a child and tonsillitis three or four times, the last attack being seven years ago. There is no history of injury. The family history is also negative. The father died two years ago from a gastric haemorrhage: the mother, three brothers, and one sister are all alive and well. None of the family or their acquaintances had ever had herpes except the patient.

I would be very interested to hear from any who have seen cases of this nature before.—I am, etc.,

J. F. BURDON,

Oct. 22. Surg. Lieut., R.N.V.R.

Surgery in a Tented Theatre

SIR,—I was much interested in Major Rex Binning's description of surgery at No. 3 General Hospital (December 7, p. 794), but I would remind him that No. 20 General Hospital was even more a tented one than No. 3, as the whole hospital, including the operating theatre and the pathology department, was under canvas. The operating theatre was in an eight-section expanding hospital tent, with single walls but double roofs, which by means of spare wall sections was partitioned into three divisions, each division being subdivided

as follows. At one end: (1) a surgeon's changing room; (2) sisters' duty room; (3) sterilizing room; (4) storage. At the other end: (1) an anaesthetic room; (2) another storage room; (3) an alcove, which gave access to a covered tented way into the adjacent hospital ward, also of eight sections. In the centre was the theatre itself, with ample room for two tables.

We were also apprehensive about infection from dust, etc., but we believe that the risk was considerably minimized by an ingenious arrangement, devised by Major Ward and Major Ghey, whereby the greater part of the theatre proper was enclosed in an inner tent made entirely of linen sheets. This inner tent was suspended from the roof. The lighting was electric from a petrol-driven engine outside the theatre. The bulbs, magnified by reflectors made from petrol tins, were fastened to a wooden frame attached to two of the upright tent poles. By a system of pulleys this could be tilted and directed at different angles. For what such evidence is worth, it may be noted that 8-inch plates were exposed in the theatre, but after twenty-four hours only grew a few colonies of *B. subtilis*, sarcinae, and moulds. No pathogenic organisms were grown.

Though our period of functioning was much shorter than that at No. 3, our list of operations, which included an appendicectomy and a mastoidotomy, showed no post-operative infection and remarkably little post-operative pulmonary complications. I heartily agree with Major Binning that the method of working proved a very valuable experience, and enabled us to realize how, by ingenuity and improvisation, a high and successful standard of surgery can be maintained even in a tented theatre.—I am, etc.,

CHARLES H. BUDD,
Colonel, R.A.M.C.

Dec. 16.

Treatment of Jaw Injuries

SIR,—I have just noticed a letter on jaw injuries by Mr. E. D. D. Davis (April 27, 1940, p. 710). He mentions that at Rouen (presumably in the last war) an efficiently equipped dental department did excellent and skilful splinting and treatment of jaw injuries. This department, which I had charge of, provided all the early treatment he advocates. About one thousand compound fractures of jaws and severe facial injuries passed through. The grouping of these cases shed a light on the best treatment of haemorrhages, and the prevention of septic pneumonia, that deadly bugbear of *pre-prontosil* days. Early suturing was the rule, and sometimes a splint would be introduced and suture undertaken under the same anaesthetic, although local anaesthesia was generally the choice.

I offered to undertake the same work before and after the outbreak of this war, but apparently such a grouping of cases is not desired, although one would think that cases in the Middle East might well be spared the puckering deformities of delayed treatment and splinting.—I am, etc.,

i/c Oral Dept., B.E.F., 1916–19.

Halton Camp, Bucks, Jan. 7.

Convulsion Therapy in the Out-patient Department

SIR,—Dr. E. B. Strauss's letter (January 4, p. 31) casts an unwarrantable aspersion on institutional psychiatrists which cannot be allowed to go unchallenged. I am unqualified to speak on the question of electrical convulsant therapy, but from a fairly extensive experience of other methods of "shock" treatment I am prepared to admit the practicability of its application to out-patients. (Some years ago in Vienna I saw insulin therapy given to out-patients apparently quite successfully.) However, Dr. Strauss seems to consider that British psychiatry does not exist outside London. The majority of mental hospital superintendents throughout the country are "consultant psychiatrists," and their out-patient clinics are, I believe, almost invariably held at the nearest general hospital. It is difficult to understand, then, why the cases seen by them should differ materially from those attending Dr. Strauss's out-patient department. A study of the annual reports of the "more progressive mental hospitals" shows clearly the excellent work being done and the large number of cases in which the necessity for mental hospital treatment is avoided. Further, with the many new admission blocks which are now attached to mental hospitals it is possible to admit early cases to pleasant surroundings, where they can receive skilled nursing attention and in which they tend to recover more rapidly than do those who prefer to receive their treatment as out-patients. Thus it is sheer nonsense, and displays a complete ignorance of the existing facilities in almost every county, to suggest that the institutional psychiatrist does not know what early mental disorder is like. One is tempted to ask whether those psychiatrists who see practically nothing but early cases are capable of giving an accurate prognosis, as they are apt to forget, if they have ever known, what an advanced psychotic patient is like.

With regard to the early development of "asylum psychosis," I have yet to see a case of this curious disorder; the number of patients who after their return home write gratefully of their treatment and their readiness to attend for "follow-up" observation suggests that it is at any rate of no serious significance, if it exists at all.

Lastly, should one speak of voluntary patients being "compelled" to enter hospital?—I am, etc.,

J. C. SAWLE THOMAS.

The Mental Hospital, Berry Wood,
Northampton, Jan. 13.

SIR,—As one associated with the introduction of the electrical convulsant treatment to this country from its inception, and who, together with my colleagues at Warlingham, has induced over 1,600 major fits upon some 130 patients since November, 1939, I feel constrained to venture an opinion regarding this out-patient application controversy. I do so with complete freedom from personally conditioned viewpoints, having practised this treatment under both in-patient and out-patient conditions with facilities for both.

Putting aside ingenious objections and unique occurrences, I know of no valid reason why electrical treatment should not be applied in the out-patient clinic by a competent psychiatrist. This is intended as a broad generalization and one based upon sheer experience—albeit predominantly institutional. That danger exists of this treatment becoming commercialized I can envisage, though that is another matter. There is danger, too, of indiscriminate application, a danger which will grow less as our criteria of selection improve—and improving they are.

One precaution we observe as a condition for out-patient treatment—namely, that every patient so treated shall be escorted by a responsible relative or friend. This precaution arises not from any of the alleged drawbacks hitherto mentioned, but because of amnesia, which in varying degrees is a transitory post-therapeutic phenomenon constantly observed.

I would add that 75% of our admissions to the Warlingham Park Hospital last year were voluntary, and from these a large proportion electrically treated were drawn. The cases treated latterly, in short, differ in no way from the out-patients and cannot be regarded as institutionalized.—I am, etc.,

WM. H. SHEPLEY.

Warlingham, Jan. 13.

Tuberculosis and Shelters

SIR,—I was glad to see Dr. C. K. Cullen's letter (January 11, p. 61) regarding the Ministry of Health's suggestion for dealing with cases of open tuberculosis known to frequent public shelters. It seems to me that the difficulties in connexion with compulsory removal to hospital of such cases have not been fully realized. By what means are such cases to be discovered? Are the confidential notification registers to be used for this purpose and the tuberculosis officers expected to act as public informers? If this is so (and apart from such a method I fail to see how cases of open tuberculosis are to be discovered), then, however unwittingly, the tuberculosis service will be dealt a death blow.

Since its inception this service has been built up on the confidence the public have shown in the dispensaries, and this confidence will be gravely impaired. People who normally are referred to a dispensary for investigation will fear to attend in case they are found to be tuberculous and be forced to accept institutional treatment because they happen to use a public shelter. Also, as Dr. Cullen points out, it will bring about the disappearance of patients from dispensary supervision. Let it be understood that once the dispensary service

loses the confidence of the public it will take many years to regain such confidence, and during the post-war period, when tuberculosis may increase, we shall find that fresh cases will not be brought to light until they have advanced beyond curability, and who meanwhile will have been infecting other people.

Although one recognizes that the tuberculous in shelters do present an undoubted danger to the general public, it seems to me that this is much exaggerated. From knowledge of East London, I am aware that only a very small number of known cases of open tuberculosis do, in practice, frequent public shelters in that area. Give the open cases of tuberculosis adequate alternative sheltering adapted to their condition and sufficiently attractive—that is, warm dry well lighted, and with a modicum of safety—and the few open cases of tuberculosis at present using public shelters should be easily persuaded, without compulsion, to use it.—I am, etc.,

London, E.1, Jan. 14. R. M. ORR-EWING.

Opening the "Register"

SIR,—The Press announces that two Orders have been made authorizing the inclusion of oversea doctors temporarily in the *Medical Register*. The first Order applies to doctors qualified to practise in Canada or the United States who are *wanted in the Emergency Medical Services*. The second applies to doctors qualified to practise in any part of the British Empire or in the countries of our European Allies, or in Germany or Italy. These men are *wanted* for service with the Allied Forces and *in approved hospitals*. Except doctors from Canada or other parts of the Empire who are British subjects, and to whom my remarks do not apply, the doctors to whom these two Orders refer are aliens. The italics are mine, and to some of your readers it may be news that doctors are *wanted* in the sense of their services being urgently needed to supply a want, either in the Emergency Medical Services or in approved hospitals.

In the London area I and those of my medical friends with whom I have compared notes complain of lack of work: the authorities will add to our discontent if any alien doctor is given any work so long as that work could be equally well done by a British doctor who is in need of employment. This may seem ungracious, but Justice has precedence over Charity—I am, etc.,

London, W.8, Jan. 15. HALLIDAY SUTHERLAND.

"Egyptian Tummy"

SIR,—I have read the various letters on the above condition and wish to add my observations. Drs. Leigh Canney and V. S. Hodson (January 11, p. 64) both ascribe this ailment to meteorological causes—namely, the rapid cooling of the body surface. During my experience as a ship surgeon on Indian and African voyages I came across this condition, which I diagnosed as a "chill," each time we came into hot weather. In every case there were two common factors exhibited: (1) each patient was making a first trip into the Tropics; and (2) each was upset by the heat and slept with either the minimum amount of clothing or none at all, and allowed the electric fan to play directly on the body.

The symptoms of three cases were those of lower abdominal pain associated with frequent and painful micturition. The remainder, about ten cases, displayed generalized abdominal pain of a "colicky" type associated with diarrhoea and malaise. In the first group chemical examination of the urine failed to detect any traces of albumin. In the second group, owing, unfortunately, to the complete lack of apparatus, etc., no bacteriological examination of the stools could be made. Questioning in each case established a negative history for dysentery or allied enteritic conditions, either recent or remote. This, coupled with the common factors mentioned above, led me to make a diagnosis of "chill."

I made inquiries about this condition from one or two ship's officers who had been on tropical voyages for several years, and they assured me that it was fairly common in "first trippers" when they first met really hot weather. The advice they had always given was to allow the fan to play directly on to the bulkhead above the bunk instead of directly on to the body, thus disseminating the force of the draught and reducing the rate of cooling, and always to cover the abdomen with something, such as the sheet rolled round like a diaper. Treatment, which was successful, consisted of local warmth in the shape of a scarf or binder wrapped round the abdomen, mild gastric sedatives, light diet, and the advice about the draught as given above.—I am, etc.,

Glasgow, Jan. 14. T. T. FERGUSON.

Perspiration and Flannel Clothing

SIR,—Dr. Leigh Canney's letters to your *Journal* (December 7, p. 806; January 11, p. 64) sound exceedingly practical, and lead me to relate a chance discovery with regard to flannel clothing in any perspiring patient.

An embryo medical student returned from a lecture by Mr R. Ablett, M.Sc. (Lecturer in Physics, Liverpool University), and related how he had demonstrated the high temperature which is created when there is a change of surface tension as moisture replaces air in flannel. Take a clinical thermometer, wrap round it a thin strip of dry flannel, place it in the mouth, and in five minutes the temperature registered by the thermometer will be 106 to 110° F. This is the temperature of the flannel and not of the mouth. An amazing temperature, therefore, will be recorded in any patient who is allowed to suck a dry handkerchief, or any part of clothing should the thermometer touch this clothing. If the axilla is dried and the thermometer and a piece of dry clothing placed in the axilla the same occurs. It has long been customary to place all sweating patients between blankets, and if these are changed when wet we are keeping our patients in a warming apparatus far superior to any electrical device.

Dr. Leigh Canney's patient was sweating in a thin nightdress. That warm Turkish towel saved her life. He is to be congratulated upon his observation.

I would like to thank Mr. Ablett for his scientific explanation.—I am, etc.,

Liverpool, Jan. 13. R. KENNON.

Human Fertility

SIR,—I was much interested in Dr. John Pryde's article (January 4, p. 12) on the study of human fertility, and in Dr. J. D. Flew's letter (January 11, p. 66) citing two cases which came under his observation and which seem to point in the opposite direction to Dr. Pryde's conclusions.

May I record a case which came under my observation a few days ago: A young married woman with one child aged 3 years living. Two previous miscarriages, the last occurring in July, 1940. Following this there was a normal menstrual period commencing on August 7, 1940. (She has a regular cycle, 5/28.) Her husband is on active service and returned for ten days' leave prior to embarkation on August 26–September 3. Coitus occurred each night during this time, which therefore was *after* the "safe period of Knaus." In this case the fertile period should have been August 17–22. On examination she was approximately twenty weeks pregnant.

In the present state of our knowledge I don't think we can rely on this "safe period."—I am, etc.,

Lydd, Jan. 15. RUPERT PALMER.

Medical Examination of Home Guard

SIR,—In reply and contradiction to Dr. L. J. Forman Bull (January 11, p. 65), may I point out that at least in the Salford Battalion of the Home Guard voluntary medical inspection of every volunteer has been in force for two months. The men have as full an examination as circumstances permit, but they are not told what their physical condition is. Instead I make a report to the C.O., and men are then placed on duties which they can easily perform. In this way the voluntary nature of the Home Guard is kept up, and so far as is humanly possible no man is called on to do work of which he is incapable.

The Director-General, Home Guard, said that he would try to make an honorary M.O. an integral part of every Home Guard battalion in the country after he had heard and seen what we have done. I hope that this answers Dr. Bull satisfactorily.—I am, etc.,

Dobeross, Jan. 17. E. WYNNE-JONES.

Adie's Syndrome

SIR,—I thought that the above term for the phenomenon in question had been accepted in both Great Britain and other countries for the sake of convenience and to avoid further wrangling on the question of priority. However, Mr. R. Foster Moore's letter (January 18, p. 99) shows me that *this is not so, and therefore I write to claim priority for my* colleague Dr. Charles Markus. What is called "Adie's syndrome" is the association of "myotonic pupil" (generally unilateral) with (apparently idiopathic) absence of tendon reflexes—absence of patellar or ankle reflexes or both. There is a tendency to regard a myotonic pupil without loss of tendon reflexes as an incomplete form of Adie's syndrome. It has even been suggested that some cases of apparently idiopathic absence of tendon reflexes, without pupillary changes, are also to be regarded as examples of incomplete Adie's syndrome.

Dr. C. Markus in October, 1905, demonstrated a boy aged 12 years (*Ophthalm. Society's Transactions,* 1906, **26**, 50) with typical right "myotonic pupil" and absence of patellar and ankle reflexes. "Myotonic pupil" had been described in Germany as early as 1902, but Markus laid particular stress on its association in this boy with absent tendon reflexes, and he even took the trouble to get me to confirm the latter phenomenon before demonstrating the case, which was in fact the first demonstrated example of what is now called Adie's syndrome. Markus at the same time suggested a pathological explanation —namely, that the change might be a local "abiotrophy" in Sir William Gowers's sense, and this explanation has not been proved incorrect. Moreover, twenty-seven and a half years later I showed the same patient for Dr. Markus at the Royal Society of Medicine (*Proceedings,* 1933, **26**, 530); the pupillary and tendon-reflex phenomena were still present as before, the patient having continued to enjoy good health; he was married and had two healthy children, and his blood serum gave negative Wassermann and Meinicke reactions. This case, therefore, confirms the benign nature of Adie's syndrome. A typical case of myotonic pupil, likewise described by Dr. Markus in 1905, was that of an old friend of mine. He is now in his seventy-sixth year and his myotonic pupil remains unchanged.—I am, etc.,

London, W.1, Jan. 18. F. PARKES WEBER.

Cut Tendons

SIR,—The interesting letters, especially the thoughtful letter of Dr. James Mennell (December 14, p. 848), prompt me to make a few remarks on this subject. I must at once say that I speak as an onlooker, not as a general surgeon. The importance of the subject must be my excuse for this letter.

When flexor tendons in the hand are cut most people give a bad prognosis for complete recovery. The out-patient sister will tell you she has rarely seen a case get perfect flexion; the matron at the nursing home and the massage sister will tell you the same; even the surgeon will warn you that adhesions are likely to form and that movement may not be complete. Mr. A. Wilfred Adams (November 30, p. 765) suggests that accurate suturing of the cut ends is the key to success. This, of course, is of the utmost importance. No doubt fine sutures and fine needles are required as well as a delicate surgical touch. How nicely an ophthalmic surgeon would do this job!

But this is only one aspect of the problem. First of all asepsis is of the utmost importance. We must expect adhesions if a septic infection of the tendon sheath occurs. Here I would suggest that the hand should be washed in running water for a quarter of an hour, and then soaked in biniodide solution 1 in 1,000, or proflavine solution 1 in 1,000, for a further fifteen minutes. Proflavine sulphate 0.1 buffered to *p*H 6.3 in distilled water has been shown by Drs. Russell and Falconer to have the minimum toxicity to tissues, while its bactericidal properties are equal to the other acriflavine preparations. It was described by Dr. Garrod in a recent discussion at the Royal Society of Medicine as the "ideal antiseptic."

Now for the problem of the tendon. This may be compared to a train running in a tube—a train which is in contact not only on the ground but also on the sides and on the roof, and separated from its walls by a lubricating fluid. The train slides to and fro in this tube. When a tendon is cut, our tube and train are cut in two. Now how are we going to join up our train without damaging the tube in which it runs? Let us take the case of a cut flexor profundus tendon. In seeking for the proximal end of the tendon, which has contracted up a couple of inches, it is customary to slit up the tendon sheath until the tendon is found; bandaging the forearm and flexing the hand will help to reduce the gap. In the case of our train, slitting up the sheath would mean cutting away the roof and most of the sides of our tube, thus collapsing the superficial structures on to our train. No matter how carefully the carriages are united together, our train would never again run smoothly to and fro. Dense adhesions must form on the roof and sides of a tendon thus exposed. The sheath is extremely thin and almost impossible to identify after it is slit up. Sewing up of the sheath over the tendon seems to be impossible, although so desirable.

Is there any way of preserving our tunnel while we look for our train? The following suggestion is purely theoretical on my part. It is that the tissues over the proximal end of the tendon should be carefully dissected down to, but not into, the sheath. Then a longitudinal slit about a centimetre long should be made about two inches from the cut end of the sheath. If the tendon can now be identified through the slit a very fine bougie can be passed through the slit up to the cut end of the sheath. Once the mouth of the sheath is identified a fine crocodile forceps could be passed up the sheath, and the cut end of the tendon drawn down. The tendon ends can then be accurately joined up with fine sutures all round their periphery and the tissues replaced.

Here the damage to our tunnel is only the cut in the roof and the slit further up. Any adhesions at these two points would not be serious and would yield to passive movement. With the usual surgical technique of slitting up the tendon sheath the outlook for good flexion of the terminal joint must be poor, no matter how early and skilfully passive movements are applied. One may ask if it is fair to leave these operations, the success of which is of so great importance to the individual, to newly qualified house-surgeons. Surely they merit the skill of the R.S.O. or one of the surgical staff, and should be treated as major operations.—I am, etc.,

Guildford, Jan. 17. T. B. JOBSON.

Too Old for Service

SIR,—The medical profession should take a definite stand upon the question of medical fitness for service. At present at one end of the scale there is flexibility, at the other end rigidity. A man of 21, for example, is assumed to be fit to be called up for service for his country's needs. If, however, he claims that he is medically unfit, then the medical examination and the medical decision is final as to fixing his place in his country's defence. A man of 70, on the other hand, is automatically disqualified for age only; the assumption is that owing to his age he is unfit and he is not allowed to disprove the assumption. A man of 21 is assumed to be fit, but he is allowed to bring evidence to prove his unfitness on medical grounds. Surely it is equally scientific for a man of 70 to submit to medical examination, and to prove thereby that he has the constitution, physical and mental, of the average man of 40 or 50. I know the economic objections that are usually raised, but they are comparatively unimportant in the face of the great principle that in the time of the country's need every man should be assessable at his scientific value and not at his age mintage.—I am, etc.,

London, W.1, Jan. 14. JOSIAH OLDFIELD.

Medical War Relief Fund

SIR,—I should like to pay a tribute of grateful thanks to the Medical War Relief Fund. As a result of enemy action my property was very severely smashed up. The committee of the fund came to my relief with a courtesy and speed which astonished me. I received a substantial loan (interest-free), which has made all the difference between a very hard knock and a crushing blow. I feel that my colleagues have come to my rescue in a noble manner, and I am proud of our profession, which has been able so quickly to raise a fund for the relief of its less fortunate members.—I am, etc.,

Jan. 19. A VICTIM OF THE BLITZ.

Obituary

CHARLES THURSTAN HOLLAND, F.R.C.S.

We regret to record the death on January 16, at the age of 77, of Mr. C. T. Holland of Liverpool, recently lecturer on radiology at the Liverpool University. Mr Holland was one of the pioneers in his specialty, and did more than any other man to further radiology and establish it as a department of medicine that could take its place on an equal footing with other special branches.

Charles Thurstan Holland, the son of the late Alderman W. T. Holland, was born at Bridgwater, Somerset. He was educated privately and at University College Hospital, qualifying M.R.C.S., L.R.C.P. in 1888. He took the Ch.M. Liverp. in 1922, became F.R.C.S. in 1928, and was made LL.D.Liverp. in 1935. After qualification he went into general practice in Liverpool and soon after Rontgen made his discovery in 1895 Holland quickly saw the possibility of applying x rays to medical and surgical problems. His enterprise and early work were quickly recognized, and he was appointed honorary radiologist to the Royal Southern Hospital, Liverpool, in 1896, where he worked in this capacity until 1904. From then until 1923 he was honorary radiologist to the Royal Infirmary at Liverpool. During the war of 1914–18 he was radiologist to the First Western General Hospital and consultant radiologist to the Western Command, holding the rank of major, R.A.M.C.(T.). In 1918 he was a member of the War Office Committee on Radiology.

Thurstan Holland was in the true sense of the word a pioneer. After he left general practice he worked in very close association with Sir Robert Jones, and this association played a great part in his success in developing and applying the new technique in his professional work. Not only did he have the vision to see the vast possibilities opened up by Röntgen's discovery, but he also had the strength of mind and forcefulness of character needed to overcome obstacles that are inevitably put in the path of the pioneer. He never hesitated to speak his mind, and his straightforward approach to problems always cleared the path in meetings and discussions when indecision seemed to prevail. As a chairman he was masterly and did not allow members of a committee to stray far from the point at issue.

So much of his time and energy were taken up by clearing the ground for the recognition of the new specialty that he was able to make few fundamental contributions to the new science. He will always be remembered as a pioneer, and as such was widely recognized in the numerous official positions he was asked to hold. The honour he most valued was his election in 1925 as president of the first International Congress of Radiology, which was held in London. He was president of the Röntgen Society in 1904 and 1916, president of the Section of Radiology at the Congress of Radiology and Physiotherapy in London in 1922, and president of the British Institute of Radiology in 1929. He was a member of the British Medical Association for fifty-four years, and was vice-president of the Section of Radiology and Medical Electricity at the Annual Meeting in 1910; president of the Section of Electrotherapeutics at the Liverpool Meeting in 1912; and vice-president of the Section of Radiology in 1932. He had a high reputation in the U.S.A. and was made an Honorary Fellow of the American College of Radiology; he deeply regretted that poor health did not allow him to be present at the fifth International Congress of Radiology, which was held in Chicago in 1937.

He published numerous papers on radiology in the medical press and was for a time a regular contributor to the *Medical Annual*. His energy and interest carried him into fields other than medicine, and he lectured on climbing and photography, being the first president of the Lancashire and Cheshire Photographers' Society. He was also Deputy Lieutenant for Lancashire. His wife died in 1924, and there was one son of the marriage.

[The photograph reproduced is by Elliott and Fry, Ltd.]

H. E. BOWER, M.D.

Dr. Harry Edward Bower, who died at his home, Viewfield, Stretton, Cheshire, on December 31, aged 74, studied medicine at Edinburgh University, qualifying M.B., C.M. there in 1887. He took his M.D. in 1905. After six years as assistant to his cousin in Weaverham he settled in Stretton, where he spent forty-eight years in family practice. He had been a member of the British Medical Association for fifty years.

Dr. L. J. PICTON writes: "Old Smith" was a character, shrewd, of disconcerting plain speech, a game shot, an archer, above all a doctor. He was generous to the many poor, to whom he never sent a bill, but, almost Robin-Hood-like, he made the very rich pay the full value of his undoubted services. Harry Bower, his roots in the soil, his formative years spent in "the Athens of the North," and his apprenticeship (in all but name) under the ripe, practical wisdom of his much older cousin, was the product of those influences on a character drawn into medicine by an interest which remained to the end unflagging. Keen but mild, with a mastery of detail which did not distract him from essentials, with a constant habit of picturing in his mind how the patient before him had come to be what he was, naturally urbane, a happy talker, appreciative of kindness, a worshipper of children, Bower was a family doctor, endowed for his task. Therapeutics was almost his hobby, and the new as familiar as the old. One innovation appalled him—the obligation to write panel "scripts." He would rather make the medicine than write it. For over a quarter of a century Bower served on the county panel committee. His balanced judgment reposed on experience begun as demonstrator of anatomy at Edinburgh University and as house-physician and house-surgeon at the Edinburgh Royal Infirmary and continued in a full range of the ordinary preoccupations of a country doctor—not least important in his eyes being his position as medical officer of the Runcorn Union. He was medical superintendent of the Isolation Hospital, Dutton, certifying factory surgeon, an honorary life member of the B.R.C.S., a J.P. for the county of Cheshire, and, during the last war, medical officer of the Oaklands Military Hospital, Daresbury, and the Raddon Court Military Hospital. At the time of his death he was a county councillor, representing the Appleton Division; he had served an earlier term in this capacity. He was a governor of the Boteler Grammar School. A Freemason, he was a member of the North Cheshire Lodge. In 1899 he married the daughter of C. T. Whitley, J.P., of Stretton, who survives him with two sons and three daughters. His eldest son, who succeeds him in practice, is now on active service.

H. C. WILSON, M.D., F.R.C.S.

We regret to record the recent death from coronary thrombosis of Dr. Hugh Cameron Wilson. He was born in Edinburgh in 1883, and was educated at George Watson's College; on leaving school he began his medical career at the University of Edinburgh. Wilson was a brilliant student, graduated with honours in 1906, and took his M.D. with a highly commended thesis two years later. He held resident appointments at the Royal Infirmary of Edinburgh for a year, and then took a single ticket to London. He was house-surgeon at the Seamen's Hospital, Greenwich, Paddington Children's Hospital, and resident surgical officer at the Great Northern Hospital. He took the F.R.C.S. in 1911 and intended specializing in surgery. The opportunity arising, he joined Dr. E. C. Montgomery in practice in Maidenhead in 1912, and in 1914 he introduced his boyhood friend, Dr. E. R. D. Maconochie, into the practice. He was soon appointed surgeon to the Maidenhead Hospital, and until his death was mainly responsible for the surgical work of the district. During the 1914–18 war he was a major in the R.A.M.C., acting as surgical divisional officer in a hospital in France.

During the past twenty-two years his skill as a surgeon has been in great demand. He was a brilliant surgeon, quick, neat, and accurate. He was a very popular and hard-working man, loved by rich and poor alike, and the humblest was treated by him in a kindly and courteous manner. His hobbies were occasional golf, fly fishing—in which he was something of an expert—and the local hospital. He was E.M.S. medical superintendent of the hospital, as well as surgeon, and took a great interest in its affairs and management, apart from his interest as a surgeon. The hospital will miss the jaunty air, quick step, and red carnation in his buttonhole, and his like will be hard to replace. He was of a somewhat retiring disposition apart from his medical world, and he took no part in public affairs. He was a true friend to many. He is survived by his widow and one daughter.

T. LAWSON McEWAN, M.B., CH.B., D.P.H.

By the death of Thomas Lawson McEwan on January 13 at the age of 48 his colleagues have lost a staunch friend and Devon its first county bacteriologist.

Dr. McEwan was educated at the Harris Academy, Dundee, and at the University of St. Andrews, where he graduated B.Sc. in 1914, with honours in chemistry, mathematics, and physics. He then went to London and continued the study of chemistry and biology at King's College, University College, and Birkbeck College. Later he became principal assistant to the public analyst for the City of Westminster and for the borough of Fulham. He was given a commission in the Argyll and Sutherland Highlanders, but was transferred in December, 1916, to the Ministry of Munitions as a research chemist. In the following year he went to the Research Department at Woolwich Arsenal. His research work there was published in the *Journal of the Society of Chemical Industry*, and he was elected F.I.C.

Wishing to take up medico-scientific work, a project which had been interrupted by the war, McEwan returned to St. Andrews to study medicine, where he was an outstanding student, and in June, 1928, graduated M.B., Ch.B. with special distinction, gaining the McEwan prize in surgery. After being house-physician at Dundee Royal Infirmary he became assistant to Prof. W. J. Tulloch, who wrote of him: "As a student of bacteriology he showed himself to be a man of outstanding ability. He was easily the best student of his year in my subject, and, indeed, was the best student of his year in the majority of the subjects in the medical curriculum. He gained the medal in the class of bacteriology, his marks being among the highest that had been recorded in the examination. Subsequently he also distinguished himself in the class of bacteriology for the D.P.H." In 1930 McEwan was appointed bacteriologist to the Devon County Council, a post he held up to the time of his death. This new department he organized with great skill and enthusiasm, and gradually built up a laboratory on first-class lines.

The indomitable courage with which he bore his long and fatal illness was what those who knew him well would have expected of him, but his death leaves a sad gap, and he did not live to see the fulfilment of his cherished and carefully laid plans of a new laboratory, upon which he had spent so much thought and time. In 1919 he married Elizabeth Holt Ogilvy, who survives him with their two daughters.

R. B. F. McKAIL, M.B., CH.B., D.P.M.

Dr. R. B. F. McKail, who died on January 10 after a long and distressing illness which he bore with great courage, was educated at Allen Glen's School, and in 1909 graduated M.B., Ch.B., with commendation, at the University of Glasgow. In his student days he won the Arnott Prize and the Black Medal and Muirhead Prize. After qualifying he worked for two years as demonstrator in the Anatomy Department in his own university. In 1911 he entered the service of the Lancashire Mental Hospitals Board at the County Mental Hospital, Prestwich, and later served under the same authority at their hospitals at Winwick and Whittingham. In the war of 1914–18 he served with the rank of captain in the R.A.M.C. in Gallipoli, Egypt, Sinai, and Palestine. He was twice mentioned in dispatches, but his health was affected, and from this ill-health he never fully recovered. On demobilization in 1920 he was appointed deputy medical superintendent at the Calderstones Certified Institution for Mental Defectives—once again under the Lancashire Mental Hospitals Board—and in 1933 became the first medical superintendent of the Brockhall Certified Institution, Langho, near Blackburn. In September, 1937, continued ill-health compelled him to retire, and he returned to his native city of Glasgow. Dr. McKail was for many years a member of the British Medical Association and the Royal Medico-Psychological Association. His wife predeceased him in 1937.

Dr. DOUGLAS J. ROSE, medical superintendent of Brockhall Institution, writes:

Having myself spent twelve years as one of McKail's junior colleagues I should like to add my personal appreciation of his remarkable ability and great personal charm. Throughout his career he was exceptionally popular among his professional colleagues, his patients, and the staffs of the institutions at which he served. Often in indifferent health, he never spared himself, but devoted himself whole-heartedly to the interests of his patients. No junior colleague ever sought his help or advice in vain. With a broad general culture and unfailing interest in men and affairs he combined a wide experience and acute clinical judgment in his own specialty. A keen follower of sport and athletics, his varied interests made him a most acceptable social companion to all sorts and conditions of men. During the last few years of his active professional life his knowledge, energy, and mastery of detail were devoted mainly to the preparation of the Brockhall Extensions Scheme, but rapidly failing health prevented him from seeing the fruits of his labours. The institution, now almost completed, will, however, stand as a tribute to his wisdom and foresight.

It is with regret that we record the death at Ross-on-Wye on January 4 of Dr. ALFRED HUMPHREY-DAVY of Bournemouth. A Galway man, Humphrey-Davy first studied engineering at the Queen's College, Galway, obtaining the B.E. degree. Directly afterwards he started to study medicine, and graduated M.D. and M.Ch. in the Queen's University in 1870. For a time he was a medical officer at Hoxton House Asylum, and later, from 1879 to 1894, he was in general practice in the Sheffield area. He moved to Bournemouth in the latter year, where he built up a considerable practice. During the last war he acted as physician to the Herbert-Home Belgian Hospital in Bournemouth. He was honorary physician to the Victoria Cripples Institution, Bournemouth, until 1929, in which year he retired from practice. The late Prof. A. Carter of Birmingham told the writer of this notice that his father once asked Sir William Jenner what he considered the essential ingredients in a physician's character. The reply was he must be "kind, honest, and dogmatic!" Certainly Dr. Humphrey-Davy had all these qualities in full measure. He was a very devoted member of the British Medical Association and was a past chairman of the Bournemouth Division and past president of the Bournemouth Medical Society. While a student at Galway he was stroke for three years of the winning team in the college boat races and was presented with a gold medal. He died a widower, leaving a son and daughter to mourn a very beloved father.—W. J. S.

AWARDS FOR GALLANTRY IN CIVIL DEFENCE

A *Supplement* to the *London Gazette* dated January 17 contains a list of awards for gallant conduct in air raids and includes the names of three medical men who have been awarded the George Medal and five others who have received commendations for brave conduct in civil defence. Dr. André Bathfield (Royal Chest Hospital, London), Dr. Henry Norman Gregg (Coventry), and Dr. Robert Lindsay (Folkestone) receive the George Medal, and Dr. Roy McGregor Barron (Eastbourne), Dr. John Fenton (Eastbourne), Dr. Alistair William MacQuarrie (Brightlingsea), Dr. Laurence Alfred Howard Snowball (Eastbourne), and Dr. Charles Keith Vartan (Hither Green) receive commendations. The official description of the gallant conduct of the George Medallists is as follows:

Dr. ANDRÉ BATHFIELD: "Dr. Bathfield, although badly cut in many places about the face and neck and bleeding profusely, assisted in the rescue, treatment, and dressing of patients and staff, and did not leave the hospital for the treatment of his own wounds until every injured person had been removed. He worked untiringly for the patients and nurses."

Dr. HENRY NORMAN GREGG: "When the City of Coventry was heavily bombed by enemy aircraft Dr. Gregg showed a high degree of courage and resource which contributed to the saving of a number of lives. While fires were raging and bombs falling, he coolly continued to go, partly on foot and partly by bicycle, from one incident to another administering morphine to those trapped in the wreckage, and applying first aid under conditions of extreme difficulty, with complete disregard for the intense bombardment and for the very real personal danger entailed."

Dr. ROBERT LINDSAY: "Two children were trapped under the debris of some houses demolished as a result of enemy action. At great personal risk to himself, Dr. Lindsay crawled through a gap in the debris and sawed through fallen woodwork so that the children might be rescued. His danger was increased by escaping gas. At another house, which was completely demolished, Dr. Lindsay crawled through a hole made in the debris to the aid of a trapped boy, cleared the boy's face of earth and rubble, administered morphine to him, and directed the operations of the rescue party. The boy was eventually released. Dr. Lindsay acted at considerable risk to himself and it was mainly due to him that the children were rescued alive."

Medico-Legal

THE MONEY VALUE OF LIFE

Before the Law Reform Act, 1934, a ground of personal action died with the person. If a man was killed in a motor accident his widow had no claim against the other party to the collision except as a dependant under the Fatal Accidents Act. By the 1934 Act the deceased man's estate was given the same rights of action as he had at the moment of his death, and by the decision of the House of Lords in Rose v. Ford the estate was held to have a claim for the man's loss of expectation of life. In the subsequent years the courts have wrestled with the problem of fixing the appropriate damages for the loss of expectation of life to persons dying at various ages and in various circumstances. At the root of the problem there always lies, of course, the absurdity of compensating a survivor for a wholly fictional wrong supposed to have been suffered by the deceased. A recent decision by the House of Lords[1] has clarified the position to some extent, while introducing some new and remarkable considerations. Viscount Simon, Lord Chancellor, declared that the right conclusion is not to be reached by applying a statistical or actuarial test. The thing to be valued is not the prospect of lengthened days, but the prospect of a predominantly happy life. In extreme old age the brevity of the expectation of life may be relevant, but in general it is of no assistance to know how many years may have been lost unless one also knows how to put a value on the years. The ups and downs of life, its pains and sorrows as well as its joys and pleasures, have to be allowed for in the estimate. Such a problem, Lord Simon suggested, might seem more suitable for discussion in an essay on Aristotelian ethics than in a court of law. Before damages are awarded under this head the court must be satisfied that the circumstances of the individual life were calculated to lead, on balance, to a positive measure of happiness, of which the victim has been deprived by the defendant's negligence. If the character or habit of the deceased were calculated to lead him to a future of unhappiness or despondency, that would be a circumstance justifying a smaller award. As Lord Wright said in Rose v. Ford, special cases suggest themselves where the termination of a life of constant pain and suffering cannot be regarded as inflicting injury, or at any rate the same injury as in more normal cases. Moreover, the question is not whether the deceased had the capacity or ability to appreciate that his further life on earth would bring him happiness. The test is not subjective. The right sum to award depends on an objective estimate of the kind of future the victim might have enjoyed. Pecuniary prospects do not come into the picture.

When the deceased is very young, there is necessarily so much uncertainty about his future that no confident estimate of prospective happiness can be made. If the deceased, on the other hand, is old enough to have settled prospects, and to have attained in some degree to an established character and to firmer hopes, his future becomes more definite and the extent to which good fortune may probably attend him more calculable. In no case, however, should the social position or prospects of worldly possession be considered. Lawyers and judges may here, Lord Simon observed with satisfaction, join hands with moralists and philosophers and declare that the degree of happiness to be attained by a human being does not depend on status.

His Lordship admitted that the jury or judge of fact is attempting to equate incommensurables. Damages which would be proper for a disabling injury may well be much greater than for deprivation of life. For these reasons, whatever the age of the deceased, very moderate damages should be awarded. In the case before their Lordships the deceased was a boy of 2½ years and the trial judge had awarded £1,200. The Court of Appeal had reduced this to £350. The House (which, because of the importance of the case, consisted of seven Law Lords) reduced this further to £200. They hoped

[1] 1937, A.C., 826.
[2] Benham v. Gambling, 1941, 1 All E.R. 7.

that the views expressed in the Lord Chancellor's judgment might help to set a lower standard of measurement for what is in fact incapable of being accurately measured in coin of the realm.

In future, therefore, when a court is asked to assess damages for loss of expectation of life, it will be open to the parties—and indeed necessary—to lead evidence to show the prospect of future happiness which the deceased had at the moment of his death. The scope of such evidence seems to be almost without limit, and to include all kinds of intimate personal, and indeed psychological, details about the deceased. Whereas the personal representatives may endeavour to show that the deceased was virtuous, hardworking, and a good husband and father, the negligent motorist may be able, by patient investigation, to show that he was a secret drinker or gambler, or kept a second establishment under another name. His intimate friends may be subpoenaed and cross-examined for information about his attitude to life; if he was ever under psychological treatment, the psychologist may be required to give a complete account of his analysis. Moreover, happiness as a basis for the value of human life seems difficult to justify either on philosophical or moral grounds. Their Lordships have given a new direction to the decision of expectation of life cases, but can hardly be said to have made that decision any easier.

Medical Notes in Parliament

The House of Commons reassembled on January 21.

On January 21 Sir ERNEST GRAHAM-LITTLE asked the Lord Privy Seal in what form questions on the advisability of adding synthetic vitamin B_1 to the war loaf were put to the Bragg Committee, whose formation was announced on June 4, 1940; whether the committee, before making its recommendations, was informed of the agreement with Roche Products, Limited; if he would now publish the Bragg Report or lay it on the Table of the House, or give reasons for not doing so; how many meetings this committee had held; when was the last; and whether it was still in existence or had been superseded by other advisory committees whose formation had been announced since the Minister's speech on July 18.

Mr. ATTLEE said that the report of the Scientific Food Committee on Bread was submitted on their own initiative. He understood that the committee was aware of the only agreement with Roche Products, Limited, then existing—namely, an agreement between that company and another company. He saw no reason in the circumstances to make a departure from the normal rule whereby reports of this nature were not published. The committee was still in existence and held regular meetings, and he deprecated giving the very detailed information asked for.

On January 21 Sir HENRY MORRIS-JONES asked the Minister of Health whether he had any statement to make concerning the admission to the *Medical Register* of alien allied doctors to assist us in the present emergency.

Mr. MACDONALD said that the Home Secretary, the Secretary of State for Scotland, and he had made an Order providing for the registration of these doctors under certain conditions.

On January 21 Dr. MORGAN asked the Secretary of State for War whether he was aware that there was grave disquiet among medical practitioners at the fact that many officers of the Royal Army Medical Corps were engaged exclusively, or principally, on administrative and non-professional work; and whether he would cause the matter to be investigated and corrected, and so reduce the demands on civilian practitioners for service with the armed Forces.

Captain MARGESSON replied that he was not aware of any grave disquiet, but it was the fact that, as happened also in civil departments, many officers of the Royal Army Medical Corps were engaged exclusively on administrative work which could not be efficiently performed by laymen. There were certain appointments which had in the past been held by medical men, but could, by an adjustment of duties, be held by non-medical men. These were now being reviewed. Some medical officers had already been replaced, and the remainder would be replaced where possible.

Mr. MACDONALD told Mr. Benson on January 21 that supplies of an insecticide selected as a result of experiment had been issued to the local authorities of the areas in which people habitually slept in public shelters. The best protection against lice was cleanliness, and local authorities had been urged to ensure that their cleansing facilities were adequate to meet the additional needs of shelterers in their areas. Compulsory powers to delouse and cleanse the persons and effects of shelterers had been obtained, and other steps to prevent the spread of lice in shelters had been taken or were under consideration.

On January 21 Dr. MORGAN asked the Secretary of State for War, having regard to the recent announcement by the Central medical War Committee about volunteers for ordinary commissions in the Royal Army Medical Corps, how many doctors had volunteered up to November 30, 1940, and had not yet been called; why volunteers were required to communicate with their Local Medical War Committee when all that that committee was able to do was to transmit names to the central committee; and if he was aware that many doctors who volunteered months ago and were told to hold themselves available were still without definite information and, consequently, in a state of uncertainty as to their domestic and professional arrangements.

Mr. MACDONALD said he was unable to give the figures asked for in the first part of the question. Many doctors who, in answer to the questionary issued before the war, expressed their willingness to serve in the Forces could not see their way to do so when approached at a later date, but he was assured by the secretary to the Central Medical War Committee that of the doctors who had in recent months applied to be recommended for commissions in the Royal Army Medical Corps very few had not yet had their names submitted to the War Office, and that accordingly the situation referred to in the last part of the question should not in general arise. If Dr. Morgan had any cases in mind and would let him have particulars he would make inquiries. Reference to the Local Medical War Committee was usually necessary to verify that the volunteer could be recruited without serious prejudice to the medical services of the area.

On January 21 Sir ERNEST GRAHAM-LITTLE asked the Prime Minister whether his attention had been drawn to the formation, by the British Medical Association, of a medical planning commission to consider problems of reconstruction and reorganization in the field of medicine in the post-war era; and whether, in view of the complexity of these problems and the importance to the public as well as to the medical profession of such reorganization, he would consider the desirability of appointing a Royal Commission to conduct this inquiry with the ultimate purpose of appointing an independent Government commission to regulate this reorganization, in place of an individual and unofficial medical association, whose recommendations could not command the general assent which would be accorded to a Government inquiry.

Mr. CHURCHILL: I am aware of this inquiry by the British Medical Association, and of similar inquiries by other bodies interested in the medical and hospital field. They will no doubt afford a useful addition to the abundant material available, in the reports of commissions and elsewhere, when the opportunity of reconstruction comes. I do not think that the appointment of a Royal Commission would in present circumstances be opportune.

Mr. MACDONALD, replying on January 21 to Dr. Morgan, said that the executive responsibility for securing the provision of adequate medical and sanitary services in public shelters regularly used for sleeping had now been devolved on the Regional Commissioners. They had the assistance of their inspectors, both medical and sanitary. If in any particular area the Commissioner were to be dissatisfied with the progress made by the local authority it would be open to him to recommend that the authority be superseded. In the City of London and the metropolitan boroughs eight doctors were in whole-time attendance at shelters, 159 more were under contract to visit shelters each night, and a further 308 were on call. The terms of service for each of these three classes were set out in Circular No. 2190, and he was not aware that there was any general dissatisfaction among the doctors whose services had been obtained.

Universities and Colleges

UNIVERSITY OF OXFORD

B.M. and B.Ch. Examinations, 1941

It should have been made clear in the notice regarding the above examinations (January 11, p. 67) that, so far as the *second* B.M. is concerned, only an examination in *pathology* will be held in March and April; there will be no examinations in any other second B.M. subjects, though there will be a complete first B.M. examination.

UNIVERSITY OF LONDON

The following candidates have been approved at the examinations indicated:

M.D.—*Branch I (Medicine)*: Margaret D Baber, R S Lowe. *Branch II (Pathology)*: S D Elliott, H Spencer. *Branch IV (Midwifery and Diseases of Women)*: Mary Kane, K Fraser M Robinson, I. E. J. Thomas. *Branch V (Hygiene)*: K [illegible] M Hart.

M.S.—*Branch I (Surgery)*: A D Le Vay.

D.Sc.—P. A. I. Goret (Guy's Hospital Medical School), R W Haines (St. Thomas's Hospital Medical School).

PH.D.—*In the Faculty of Medicine (Non-clinical)*: H Kwiatkowski.

ROYAL CANCER HOSPITAL (FREE)

ACADEMIC POSTGRADUATE DIPLOMA IN MEDICAL RADIOLOGY—D. Andrew, H. F. Francis, J. J. Richmond.

EPIDEMIOLOGICAL NOTES

Infectious Diseases for the Week

In England and Wales the four commonest infectious diseases in this country—diphtheria, scarlet fever, measles, and whooping-cough—declined in incidence slightly compared with the previous week, but in London there were notable increases in respect of all four. In Scotland the notifications for diphtheria and whooping-cough rose, especially of the former. The tardy rise in the incidence of infectious diseases in London is naturally ascribed to the effects of evacuation, but in view of the abnormally low incidence of these diseases in 1939 it is possible that the 1938 level may be exceeded before those that have remained have acquired immunity through attack. Notifications of acute poliomyelitis have risen slightly, and the figures for dysentery are nearly double those of the previous week.

Dysentery.—Although twenty-one administrative counties were affected, in only seven were more than 5 cases recorded—namely: Kent 36 (all in Tonbridge R.D.); London 23 (St. Marylebone 16, and 1 each in the boroughs of Camberwell, Finsbury, Hackney, Shoreditch, Wandsworth, Westminster, and Woolwich); Lancaster 18 (Preston R.D. 12, Whiston R.D. 3, Leigh M.B. 2, Manchester 1); Warwick 13, all in Birmingham; Surrey 11 (Reigate M.B. 8, and 1 each in Epsom and Ewell M.B., Coulsdon and Purley U.D., and Banstead U.D.); Leicester 9 (Market Bosworth R.D. 8, Leicester 1); Yorks, West Riding, 7 (Sheffield 4, Wakefield 2, Huddersfield 1). It is evident that, in relation to the numbers at risk, rural communities are affected much more heavily than urban centres, as is commonly observed when infection is conveyed through the alimentary tract. Although the figures for deaths are not available, the case fatality is probably low, as the mild Sonne form is the prevalent type at present.

Influenza.—A hint of the possible appearance of influenza in epidemic form is given by the rise in the pneumonia (primary and influenzal) figures, which exceed those of 1939 and 1938. From other countries reports have arrived of outbreaks of mild influenza in epidemic form among European countries: from Ireland, especially in the city of Cork; from Stockholm, where the disease is extremely contagious although mild; from Belgrade, where more than 60,000 cases have been recorded; and from the United States of America, notably in Memphis (45,000 cases). Boston (20,000 cases among school children), and in Western Virginia, where the epidemic is regarded as the worst since 1918.

No. 51 for 1940

INFECTIOUS DISEASES AND VITAL STATISTICS

We print below a summary of Infectious Diseases and Vital Statistics in the British Isles during the week ended December 21, 1940.

Figures of Principal Notifiable Diseases for the week and those for the corresponding week last year, for (a) England and Wales (London included), (b) London (administrative county), (c) Scotland, (d) Eire, (e) Northern Ireland.

Figures of Births and Deaths, and of Deaths recorded under each infectious disease are for (a) The 126 great towns in England and Wales (including London), (b) London (administrative county), (c) The 16 principal towns in Scotland, (d) The 13 principal towns in Eire, (e) The 10 principal towns in Northern Ireland.

A dash — denotes no cases; a blank space denotes disease not notifiable or no return available.

Disease	1940 (a)	(b)	(c)	(d)	(e)	1939 (Corresponding Week) (a)	(b)	(c)	(d)	(e)

Stillbirths	204	14	32			260	36	45		
Rate per 1,000 total births (including stillborn)			38					51		

* Notification in certain administrative areas only.

† Includes primary form in figures for England and Wales, London (administrative county), and Northern Ireland.

‡ Since January 1, 1940, figures for London (b) have been for deaths from all forms of pneumonia; the corresponding figures for 1939 relate to deaths from lobar pneumonia only.

The Services

CASUALTIES IN THE MEDICAL SERVICES

ROYAL ARMY MEDICAL CORPS

Major GORDON ALAN MACDONA LINTOTT died on active service in December, 1940, while serving in Egypt. He received his medical education at Guy's Hospital and qualified M.R.C.S., L.R.C.P. in 1931, becoming M.R.C.P. in 1934. He also took the degrees of M.B., B.S. of the University of London in 1932 and proceeded M.D. in 1936. He had held the posts of medical registrar and tutor, demonstrator in physiology and pathology, and house-physician and out-patients' officer at Guy's Hospital, and before the war was clinical tutor at the hospital. He will be remembered for his critical examination and report on the routine of water divining carried out in the physiological department of the hospital. He mastered the technique of gastroscopy under Henning in Germany and subsequently visited many clinics in the United States of America, returning with much valuable fresh knowledge. On the outbreak of war, by which time he had established a reputation as a sound clinician and an able teacher, he remained at the hospital in the Emergency Medical Service as physician in charge of the medical unit, until he felt that he was still not putting out enough effort, when he joined the R.A.M.C. as major.

Medical News

Sir Walter Langdon-Brown will give a Chadwick Public Lecture entitled "Mental Health in Wartime" on Tuesday, February 4, at 2.30 p.m., at the Royal Society of Tropical Medicine and Hygiene, 26, Portland Place, W.1.

A conference on A.R.P. is to be held on February 2, from 10.30 a.m. to 4 p.m., at Islington Central Library, 68, Holloway Road, N.7. The conference is convened by the Association of Architects, Surveyors, and Technical Assistants, and by the National A.R.P. Co-ordinating Committee. Their aim is to bring together for discussion technicians who are qualified to solve the urgent problems of A.R.P., and administrative officers who are not satisfied with the present state of affairs. Shelters, the care of those bombed out, and medical problems are among the subjects scheduled for discussion and on which a free exchange of opinion will be encouraged. Drawings and models of various types of shelter will be on view.

It is learnt that vitamin C, given in sugar tablets, is to be distributed daily, free of cost, to all children between the ages of 10 and 14 who live in thickly populated districts of Germany or territories incorporated into the German Reich. The order is effective from February 1 to May 31 in all regions except where fruit and vegetables are plentiful. Vitamin C tablets have already been distributed on an experimental basis free throughout the Reich. The resistance to infection was found to increase, and between December 15, 1940, and March 31, 1941, the treatment was extended to newly born children with good results.

The *Scotsman* reports steady progress in the campaign to immunize children against diphtheria in Edinburgh. Up to January 17, being the end of the sixth week of the scheme arranged by the Public Health Department, contact had been made with 20,387 children, and of these 15,438 had received the two inoculations necessary to complete immunization. Of the completed immunizations, 1,983 were given at child welfare centres, 2,800 at schools, and 7,933 at first-aid posts throughout the city. The number of immunizations carried out by private medical practitioners up to the same date was 2,722, and fresh batches of certificates are reaching the medical officer of health from this source every day.

Even if the evacuation of children is causing some unexpected psychological problems, it is at least satisfactory to note that the children in a much more dangerous and difficult position are being given sympathetic consideration by the authorities. Mrs. Creswick Atkinson, a member of Lord Horder's Committee, a well-known broadcaster on child welfare and a former British Red Cross worker, has been moved from her post as technical adviser to the Women's Voluntary Services in order that she may take up a full-time paid appointment as organizer of welfare work for women and children who use the large air-raid shelters of London. Mrs. Atkinson will advise local authorities on the organization of welfare work in those shelters holding 500 or more people. She will work in collaboration with Mr. Charles Key, M.P., London Regional Commissioner for Shelters. Mr. Key states that, while dispersal remains the policy of the Government, and while one of the new organization's tasks will be to persuade mothers to evacuate their children, it must be expected that the large shelters will still be much used. Of the 81,000 children still in London, 60% have not attended school since last July and are badly in need of the care and guidance which the new body of welfare workers will provide.

Letters, Notes, and Answers

All communications in regard to editorial business should be addressed to THE EDITOR, BRITISH MEDICAL JOURNAL, B.M.A. HOUSE, TAVISTOCK SQUARE, W.C.1.

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* alone unless the contrary be stated.

Authors desiring REPRINTS of their articles must communicate with the Secretary, B.M.A. House, Tavistock Square, W.C.1, on receipt of proofs. Authors over-seas should indicate on MSS. if reprints are required, as proofs are not sent abroad.

ADVERTISEMENTS should be addressed to the Advertisement Manager (hours 9 a.m. to 5 p.m.). Orders for copies of the *Journal* and subscriptions should be addressed to the Secretary.

TELEPHONE No.—B.M.A. and *B.M.J.*: EUSTON 2111.

TELEGRAPHIC ADDRESSES.—EDITOR, *Aitiology Westcent, London*; SECRETARY, *Mediscra Westcent, London.*

B.M.A. SCOTTISH OFFICE: 7, Drumsheugh Gardens, Edinburgh.

QUERIES AND ANSWERS

Premenstrual Mammary Swelling

Dr. ROSAMOND BISCHOFF (Luton) writes: I should like to know if any of your readers could tell me how to treat patients who suffer from swollen, painful breasts before menstruation. I have one patient who has considerable pain and slight swelling for two weeks before each period. Menses are regular and of moderate amount. She has been married six years but has no children. Examinations of breasts and pelvis are negative. Other patients have this complaint in a lesser degree and for a shorter period. My cases are all in nulliparae with normal menstrual history and negative examination. Would any form of hormone therapy be advisable?

Income Tax

Reduction in Net Earnings

"R. H." was mobilized in September, 1939, and has since employed an assistant. His aggregate income as assessed for the year to April 5, 1940, was not sufficiently in excess of his aggregate earned income for that year to justify a claim for relief. How does he stand for 1940–1?

*** Presumably the profits of the practice will have fallen still further for 1940 owing to the fact that an assistant will have been paid for the whole of that year. It may therefore be that the difference between aggregate income as assessed (taking the practice profits at the 1939 figure) and the aggregate actual earned income for the year to April 5, 1941, will satisfy the 20% condition and relief will be due. (N.B.—In calculating the actual income from the practice "R. H." can if he prefers compute it for the year to April 5, 1940, as 3/4 of the 1939 profits plus 1/4 of the 1940 profits, and it may be worth reviewing the position for that year now that the 1940 figures are available.)

LETTERS, NOTES, ETC.

Diphtheria Incidence: A Small-pox Analogy

Dr. ROBERT ANDERSON (Birmingham) writes: Dr. R. M. Courtauld (January 18, p. 106) may find the explanation he wants in Glasgow's experience of small-pox epidemics in 1900 and 1901. In 1900 there were about 2,000 cases of small-pox and over 400,000 people were revaccinated—about half the population. In 1901 there was another epidemic of about 500 cases. Not one of the 400,000 revaccinated people contracted the disease. This was an experiment in immunization on a large scale.

SUPPLEMENT TO THE
BRITISH MEDICAL JOURNAL
LONDON SATURDAY JANUARY 25 1940

TEMPORARY REGISTRATION AND EMPLOYMENT OF FOREIGN AND OTHER OVERSEA MEDICAL PRACTITIONERS

Reference was made in the *British Medical Journal* last week to the *Medical Register* (Temporary Registration) Order, 1941. There is given below a fuller account of this Order and an explanation of the procedure to be followed by foreign and other oversea medical practitioners seeking employment and by hospitals wishing to secure their services.

The general effect of the Order is to empower the General Medical Council to register temporarily in the Colonial List or in the Foreign List of the *Medical Register* certain foreign and other oversea practitioners who have been selected for medical commissions in the Armed Forces of the Crown or in an Allied or Associated Force, or for employment as medical officers in certain hospitals, institutions, or services (not involving medical attendance on patients in their own homes).

APPROVED HOSPITALS AND SERVICES

The hospitals and services which are approved for the purpose of the Order are as follows: (*a*) hospitals provided by local authorities or by combinations of local authorities; (*b*) other hospitals included in the Emergency Hospital Scheme (including what are known as "suspended" hospitals but not those which have been withdrawn, temporarily or otherwise, from the Scheme); (*c*) service at or in connexion with any first-aid post provided by a scheme-making authority under the Civil Defence Acts.

The Minister (i.e., the Minister of Health in relation to England and Wales, the Secretary of State for Scotland in relation to Scotland, and the Home Secretary for Northern Ireland in relation to Northern Ireland) will be prepared to consider applications for approval of any further hospital, institution, or service under the Order.

DEFINITION OF "HOSPITAL"

The term "hospital" is defined in the Order as including:

(*a*) Any sanatorium, convalescent home, or public assistance institution.

(*b*) Any institution within the meaning of the Mental Treatment Act, 1930, or institution, certified house, or approved home within the meaning of the Mental Deficiency Act, 1923, or any institution within the meaning of the Lunacy (Scotland) Acts, 1857 to 1919, or certified institution, certified house, or approved home within the meaning of the Mental Deficiency and Lunacy (Scotland) Act, 1913, or any public mental hospital or registered institution within the meaning of the Mental Treatment Acts (Northern Ireland), 1932.

(*c*) Any clinic, dispensary, hospital centre, or out-patient department.

PRACTITIONERS COVERED BY THE ORDER

Effective applications for temporary registration under the Order can be made only by practitioners who are by law entitled to practise in one of the following countries or in any of the oversea territories or possessions of one of these countries: (*a*) The British Dominions, Colonies, Protectorates, and Mandated Territories; (*b*) Belgium, Czecho-Slovakia, France, Greece, Holland, Norway, and Poland; (*c*) Germany and Italy.

Registration is subject to the conditions that the applicant is of good character, that he has been selected for one of the forms of employment defined in the Order (see above), and (in the case of a practitioner selected for civilian employment) that he holds a medical diploma or diplomas recognized by the General Medical Council for the purposes of the Order as furnishing a sufficient guarantee of the possession of the requisite professional knowledge and skill.

PROCEDURE TO BE FOLLOWED BY HOSPITALS

A hospital or service requiring the services of a practitioner should apply in all cases to the Secretary of the Central Medical War Committee at B.M.A. House, Tavistock Square, W.C.1. The Committee is compiling a list of practitioners available for civilian medical employment under the Order, and will supply names, with particulars of nationality, age, qualifications, and experience, in response to requests from approved hospitals and services. Having selected a practitioner for the vacant appointment, the hospital should notify the Central Medical War Committee, which in turn will notify the General Medical Council. The practitioner's application for registration will then be sent by the Committee to the hospital for completion, and when all the necessary formalities have been complied with the hospital will be informed by the committee that registration has been effected.

PROCEDURE TO BE FOLLOWED BY PRACTITIONERS

An oversea practitioner seeking registration and *civilian* medical employment under the Order must first apply to the Central Medical War Committee for inclusion of his name in the list of available practitioners. Interviews cannot be granted and *application must be made in writing*. When notifying him that his name has been included in the list the Committee will send the practitioner (1) a form on which he will be asked to supply particulars of his qualifications, experience, etc.; (2) a form of application for registration; and, in the case of a foreign practitioner, (3) a form of application for an Aliens War Service Department permit. The practitioner, having completed these forms, will return them to the Central Medical War Committee: and when the practitioner has been selected for an appointment the Committee will immediately commmunicate with the appropriate authorities in order that all the necessary formalities may be completed without delay. In the case of a foreign practitioner the Committee will inform the General Medical Council when the Aliens Department of the Home Office, in consultation with the Aliens War Service Department, has given notification that it raises no objection to the practitioner's name being placed on the *Medical Register* with a view to employment covered by the Order: and when employment has been offered and registration has been effected the Committee will notify the Aliens Department, and the practitioner will be asked to send his Police Registration Certificate to that Department for endorsement.

The Order does not affect the operation of the Aliens Acts and Orders or the Minister's circulars governing the employment of aliens of enemy nationality in emergency hospitals. The registration of a practitioner who has been selected for approved civilian medical work will not, for example, exempt him from the restriction imposed on him as an alien in regard to entering a protected area.

PRACTITIONERS ALREADY REGISTERED

There are a number of practitioners who are by law entitled to practise in one of the territories specified in the Order, but who have not hitherto been able to obtain work in this country despite the fact that their names already appear in the *Medical Register*. Such practitioners, if they wish to obtain civilian medical work of the kind approved for the purpose of the Order, should make application in the way indicated above, but it will, of course, be unnecessary in these cases for any application to be made to the General Medical Council.

MEDICAL COMMISSIONS IN H.M. FORCES

It is anticipated that the appointments offered to foreign practitioners covered by the Order will almost invariably be in civilian employment and that only in exceptional circumstances will vacancies exist for such practitioners in the Medical Branches of the Armed Forces of the Crown. The Central Medical War Committee, therefore, does not propose to include such practitioners among those nominated for medical commissions in response to the routine demands received from the Services; but if any foreign practitioner wishes particularly to have his name considered in this connexion he should notify the Committee accordingly.

THE NEW WAR DAMAGE BILL

BY

HENRY ROBINSON, M.D., D.L., J.P.

Honorary Secretary, Medical Insurance Agency

The medical profession is deeply concerned and quite properly much interested in the provisions of the War Damage Bill now before the House of Commons. It has already become clear that it will receive the careful attention of members in both Houses; and it is likely that many amendments will be proposed, some of which will no doubt find acceptance, before it finally emerges as an Act. All sorts of questions arising from it demand and will receive the attention of the Medical Insurance Agency on behalf of the profession as a whole. To set forth a few of them may be of interest and serve to indicate some of the difficulties.

Professional and private premises present few problems: they are to be insured compulsorily and dealt with by the Revenue authorities on the basis of the Schedule A assessments in regard to value and, therefore, to premiums. As the Bill at present stands it would appear that, besides professional premises, equipment of all sorts (furniture of surgeries or consulting-rooms, instruments, textbooks, and so forth) is to be within the "business scheme" part of the compulsory section, with a limit of £1,000. Not many doctors own property of this kind exceeding that limit of value, but there may well be owners of *x*-ray plants, radium, etc., to whom this means an under-insurance. It is not perfectly clear from the wording that the contents of the residential part of the doctor's house are excluded, and it might be worth the while of the Parliamentary Medical Committee to have the point elucidated.

As regards private goods and chattels, the insurance contemplated is entirely optional. An upper limit of £1,500 is set, and a flat rate of premium at 30s.% per annum. These insurances are to be carried out, not through the Revenue authorities, but through fire insurance companies or through Lloyd's underwriters. What is to be done if there is an existing ("peace") policy of more than £1,500? Normally, where insurance is taken out for a sum less than the full value of the goods the principle of "average" is applied; but with a maximum fixed by law, any under-insurance is not the fault of the insured person, and it seems inequitable that he should suffer in pocket on that account. It will be of interest to discover, if possible, the reactions of the insurance companies on this matter. Possibly it may be in the minds of the framers of the Bill that peace and war risks will be dealt with on quite separate bases, and that "average" should apply only to cases of gross under-insurance on a peace policy and not at all to a war one. Another point is this: if an owner has a (peace) policy of, say, £2,000 on his furniture and chattels and can find a company to accept a war risk on £500, will he be free from the danger of "average" on his full £1,500 of insurance under the Act?

Further problems may arise, unless Parliament anticipates them during the progress of the Bill, over the insurance of a houseful of chattels which belong to various owners: many people just now have their furniture, or some of it, stored in other people's houses. Presumably the £1,500 limit applies to individual owners, not to individual houses. Possibly the normal provisions of existing "comprehensive" policies may be made to apply, whereby visitors' effects are considered to be covered up to a specified percentage, but this does not cover the question of the limit, and the whole position needs clarification.

Many difficulties are likely to be met with over questions of valuation of destroyed property. Professional inventories are so difficult to obtain at present, and so expensive when they can be obtained, that many knotty points will arise—and probably many heart searchings, too—when claims for compensation are put forward in respect of chattels of which no detailed inventory or accurate valuation has been on record, or when the records have been destroyed also.

For months past the Medical Insurance Agency has been procuring quotations from assurance offices for war-risk policies in respect of life, and has negotiated a large amount of business on behalf of the profession. It seems clear that the need for this supplement to normal assurance cover is as great as ever, for the compensation provisions under the Bill for dependants of civilians killed in air raids will be quite insufficient for the needs of the widow and children of a medical practitioner, whose breadwinner has been taken from them, especially as there is often to be borne as well a heavy depreciation in the goodwill of the practice. The Agency has accumulated a wide experience of these policies, all of which is at the service of those who have dependants to provide for.

EMERGENCY MEDICAL SERVICE

CLASS I AND CLASS II OFFICERS

Following prolonged negotiations between the Ministry of Health and the Advisory Emergency Hospital Medical Service Committee, agreement has been reached in regard to the position of Class I and Class II officers as from January 1, 1941, when the existing guaranteed period of service expired.

(1) Holders of Class I or Class II contracts will be given a further guarantee of employment under their existing terms of service until August 31, 1941, thus completing approximately a second period of twelve months from the outbreak of war. Thereafter service will be subject to termination on one month's notice on either side.

(2) In the case, however, of individual officers whose services are no longer required under their present contracts, the Minister reserves the right not to offer them a further guarantee of employment but to terminate their employment on one month's notice, with or without the offer of a Class III contract—that is, a contract on a sessional basis. Moreover, any guarantee of employment will cease to apply where the officer, being within an age group required to register under the National Service (Armed Forces) Act, 1939, is recommended by the Central Medical War Committee, with the Minister's concurrence, for a commission in the Medical Branch of one of the Fighting Forces under the procedure established in pursuance of that Act.

(3) The Minister further proposes to continue on their present basis the arrangements for paying the travelling expenses of Class II practitioners.

(4) The Minister intends to offer to Class I practitioners receiving salaries of £550 per annum the option of transfer to part-time service at the rate of £360 per annum plus a travelling allowance, or in the case of officers required to live away from home free board and lodging, or £100 in lieu

ANTISEPTIC SNUFFS

BY

M. E. DELAFIELD, M.B., B.Ch.

EDITH STRAKER, M.B., B.S.

AND

W. W. C. TOPLEY, M.D., F.R.C.P., F.R.S.

Emergency Public Health Laboratory Service London School of Hygiene and Tropical Medicine

Much time and thought have been given in recent years to studying the ways in which harmful bacteria and viruses pass from one person to another, and to devising methods by which such passage can be prevented. We have come to realize more clearly than we did the multiplicity of the avenues involved, and we have found some methods which should at least tend to decrease the traffic along them. Reference to recent papers by Andrewes (1940), van den Ende and others (1940), and Miles and others (1940) will show the magnitude of the problem and illustrate the methods by which it is being attacked. In addition to the primary essentials of good ventilation, the avoidance of overcrowding, and the adequate spacing of beds in sleeping quarters and in hospital wards, they include such measures as the use of aerosols or ultra-violet light to kill bacteria in the air, the use of spindle oil to prevent those that fall to the floor from rising again as dust, the avoidance of infected fluff from blankets, and the use of masks, worn either to protect other people from the wearer or the wearer from his environment, including other people. In attempts to prevent cross-infection among the wounded the whole range of surgical technique in the wards has been reviewed, and suggestions have been made for its improvement.

There is one conclusion to which, we think, all workers in this field will subscribe. There is no sovereign remedy. If the problem is solved it will be by strengthening all possible defences, not by developing some and neglecting others; though we may be able to allot priorities when we know more than we do now about the relative importance of the various channels of infection.

Some six months ago we started to approach one aspect of the problem from another angle. Of the many methods so far practised or advocated, most are aimed at reducing the concentration of bacteria or viruses in the air. The mask is the only measure at present in common use for preventing the passage of micro-organisms from or to the nose and mouth of its wearer. The mask will certainly be retained as an integral part of any aseptic hospital technique, and it may be possible to encourage its use as a method of personal protection in the presence of unusual risks; but for this purpose it is an inconvenient instrument, unlikely to be worn continuously or by a large proportion of all those exposed to infection or those capable of infecting others. If it were possible to replace it by some method of personal antisepsis something might be gained. It is this possibility that we have tried to explore.

If it is to be applicable on a wide scale and in a variety of circumstances any method chosen must fulfil the following conditions: (1) it must be easy to apply personally; (2) its application must not itself involve any risk of cross-infection; (3) it must maintain an adequate concentration of the antiseptic material in the right situation over prolonged periods of time; (4) it must be non-toxic, even when used continuously for weeks or months.

Among the methods that have often been advocated for personal prophylaxis is the use of antiseptic gargles. As a recent instance Young and Charteris (1940) state that they have obtained favourable results by the use twice daily of an acriflavine gargle in throat-and-nose wards.

A gargle is easy to apply personally under hospital or home conditions, and given a suitable antiseptic it is non-toxic. Unless a separate glass or vessel is supplied for each gargler, and care is taken that there is no sharing, the method is by no means free from the risk of itself providing an avenue of cross-infection. It produces its result mainly in the mouth and tonsillar region, and to a much less extent in the nasopharynx. It is doubtful whether, even in these situations, an adequate concentration of antiseptic can be maintained for very long after gargling. To maintain a bactericidal or bacteriostatic concentration throughout the twenty-four hours it might well be necessary to gargle a dozen times or more. The method will have no effect on the nose. For these reasons it did not seem to be a promising method of approach.

An antiseptic snuff seemed to offer better hopes of success. It is extremely easy to apply personally. Distributed in a separate container to each person it involves no risk of cross-infection in its application. Being in the form of a powder it adheres to the mucous membrane of the nasal cavities, and to some extent to the nasopharynx. In each person it will follow the course of the inspired air currents. There is, it may be noted, an extensive literature on the direction of these currents, which is summarized by Lucas and Douglas (1934). If the snuff is, at least in part, in the form of particles of the same order of size as a bacterium it is probable that the distribution of inspired bacteria and inspired snuff will be approximately the same. Being in the form of a powder the antiseptic will probably be dissolved slowly in the nasal mucus; and it should be possible to maintain an adequate concentration of any selected antiseptic for a period of days or weeks by relatively few daily applications. We decided, therefore, to study the effects of antiseptic snuffs.

Methods Employed

The main object that we had in view was to find some antiseptic snuff that would prevent the successful lodgment and multiplication of bacteria entering with the inspired air; but it seemed improbable that we should learn much from experiments with purposely inspired bacteria, since recognizable non-pathogens would not survive long in any case. We decided, therefore, to study the effect of our antiseptic snuffs on the existing flora of the nose and throat. It seemed probable that if these reagents proved capable of eliminating, or of greatly reducing in number, one or more of the potentially pathogenic species that are often present in the nose or throat they would suffice to hold in check fresh entrants of the same species.

Preliminary experiments with nasopharyngeal washings and with swabs taken and plated in the customary way convinced us that neither of these methods offered any hope of obtaining quantitative findings of the kind that we required. It also became clear that we should have to elaborate our method, taking separate samples from each nasal cavity, from each tonsil, and from the nasopharynx, in each subject under test. The technique finally adopted was as follows.

All subjects under test were examined three times a week on consecutive days. Using a head-mirror and a nasal speculum, separate swabs were obtained from the left and right nasal cavities, care being taken to sample the anterior end of the middle turbinate whenever possible, and the anterior portion of the middle meatus. Using a tongue depressor, three more swabs were taken, one from the left tonsil, one from the right tonsil, and one from the nasopharynx. The swabs used were as nearly as possible of the same size and were mounted on wooden handles.

As soon as it was taken each swab was emulsified in 2 c.cm. of nutrient broth contained in a 5-c.cm. screw-capped bottle. The swab was rotated twenty times and then pressed against the side of the bottle; and this procedure was repeated three times. The swabs were then discarded. After allowing any obvious particles to settle, the fluid was drawn up in a sterile dropping pipette (50 drops to 1 c.cm.), and 30 drops were allowed to fall in the centre of a sterile 4-inch Petri dish. A sterile 7-cm. No. 1 Whatman filter paper was then lowered on to the Petri dish with sterile forceps, when, as had been found in preliminary experiments, it quickly took up the 0.6 c.cm. of fluid without leaving more than a general dampness on the bottom of the dish. The filter paper was then lowered with sterile forceps on to the surface of a blood-agar plate. As soon as contact had been made it was removed and discarded.

The plates were incubated at 37° C. for forty-eight hours and a preliminary examination made after twenty-four hours. After the full period of incubation they were placed in a blackened box, illuminated with strip lights, and photographed with a Leica camera giving a reduction of approximately 1:4.

At the twenty-four-hour and forty-eight-hour examinations of the plates the colonies were inspected, and films were made to determine the morphology of the bacteria present. In the case of staphylococci, in addition to examining for pigment formation, coagulase tests were done on colonies from many plates, but not from all. So far as other organisms were concerned no attempt was made to carry identification further than colony form and microscopical examination, except that doubtful colonies of pneumococci were tested for bile-solubility and the few haemolytic streptococci for the production of soluble haemolysin.

Although this method gave us better quantitative results than any other that we tried it will be clear that the sampling has remained inadequate, and that large variations must be expected apart from any treatment.

Fig. 1 shows the plates obtained from the right nasal cavity, nasopharynx, right tonsil, and left tonsil of a person not carrying any considerable number of bacteria in the nose. These five plates give a fair average picture of the results obtained with those persons who are not nasal carriers. The tonsils almost always give heavy growths, the nasopharynx less heavy, while the nasal cavities yield few colonies or none.

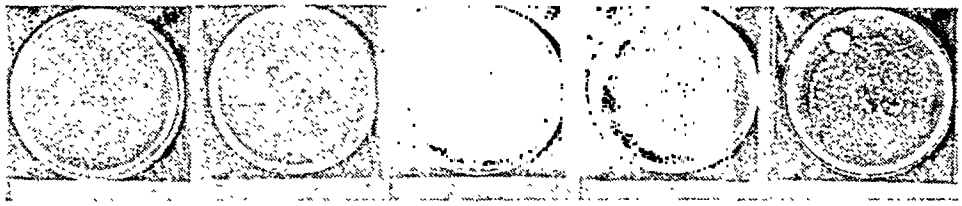

FIG. 1.—Normal Subject. Left to right, blood-agar plates from right nasal cavity, left nasal cavity, nasopharynx, right tonsil, left tonsil. No treatment.

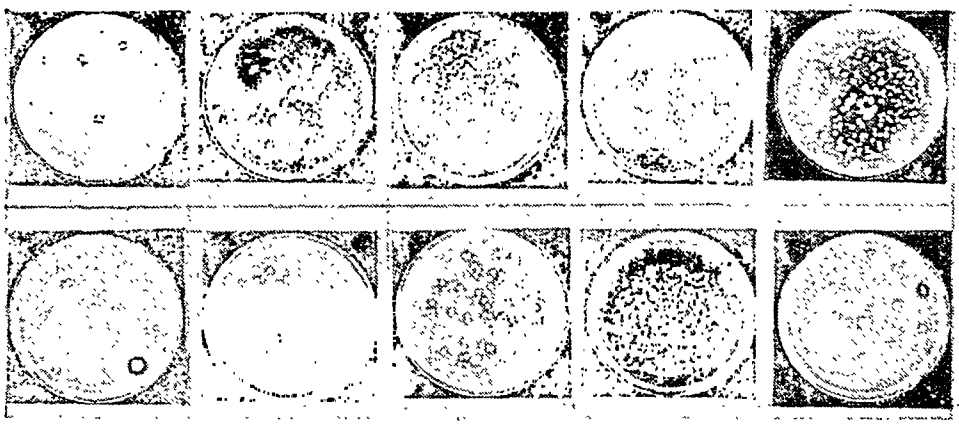

FIG. 2.—*Rows 1 and 2.* Subject C. Five successive blood-agar plates from right nasal cavity (Row 1) and from left nasal cavity (Row 2). No treatment.

Fig. 2 shows the results of five successive nasal swabbings in a subject (C) carrying staphylococci. The plates in the first row are from the right nasal cavity, those in the second row from the left. They show the kind of variation that can be expected as the result of differences in sampling, apart from any treatment.

The Antiseptic Snuffs Tested

In preliminary experiments, and before our technique of sampling had been fully developed, we tested a variety of materials, including ordinary tobacco snuffs, and lycopodium snuffs containing sodium sulphate with or without menthol, to see whether the stimulation of the normal nasal secretion would have any bactericidal effect. The results were not promising, and by the time that we had arrived at the methods outlined above we were using snuffs containing proflavine, penicillin, or sulphathiazole, with lycopodium powder or magnesium carbonate as a base. Sulphathiazole was selected in preference to other sulphanilamide compounds because of its greater action on staphylococci. Some snuffs had menthol added, some had not. The only snuffs that need be considered further are the following.

Proflavine Snuff:
5 parts by weight proflavine
5 „ „ „ menthol
90 „ „ „ lycopodium

Penicillin Snuff:
1 part by weight penicillin
5 parts „ „ menthol
94 „ „ „ lycopodium

Sulphathiazole Snuffs:
10 parts by weight sulphathiazole
5 „ „ „ menthol
85 „ „ „ lycopodium

10 parts by weight sulphathiazole
1 part „ „ menthol
89 parts „ „ magnesium carbonate

10 parts by weight sulphathiazole
90 „ „ „ magnesium carbonate

In the case of sulphathiazole we purposely started with minimal doses, to see whether we could obtain significant effects with amounts that would almost certainly prove non-toxic even when taken over long periods. The magnesium carbonate was substituted for the lycopodium because of the possibility that the continued inhalation of lycopodium spores might induce a hypersensitivity. For the small sample of penicillin at our disposal we are indebted to Prof. Florey. The properties of the crude substance as originally described by Fleming (1929, 1932) and by Fleming and Maclean (1930), together with the curative or protective effect of the purified product and its absence of toxicity (Chain and others, 1940), led us to hope that this might be a particularly favourable material for our purpose.

Results with Nasal Carriers of Staphylococci

In all we have examined 20 persons, the number of swabbings made from each varying between 16 and 32. None of the snuffs we have tested has had any detectable effect on the bacterial flora of the nasopharynx or tonsils. That they reach the nasopharynx can easily be demonstrated. With snuffs containing proflavine a trickle of yellow mucus can often be seen passing in a narrow stream from the posterior nares, frequently on one side only. With any lycopodium snuff the spores can easily be detected in swabs from the nasopharynx, and sometimes from the tonsillar region. It is probable, however, that the distribution is localized, and that the bactericidal substance employed reaches an effective concentration only in a few areas.

When it became clear that the only demonstrable effect of the snuffs was exerted on the nose, we examined, for nasal carriers of staphylococci, as large a number of subjects as were available. Those we discovered are included in the 20 subjects referred to above. In these carriers we swabbed the nasal cavities only, reserving complete swabbings for the six subjects who had formed our experimental material from the start of the investigation.

The results are not of a kind that can usefully be tabulated or be submitted to any statistical tests. All subjects were examined on three or more occasions before any treatment was begun. Some were given one variety of snuff only. Others who failed to respond to one snuff, or whose nasal staphylococci returned after temporarily disappearing or lessening in number, were subsequently treated with snuff of another kind. All that can usefully be done is to give some illustrative examples.

Penicillin

Four subjects in all were treated with penicillin snuff—this small number being due to the small supply of penicillin available. One subject was treated with penicillin alone. In three subjects a short treatment with penicillin was followed by further treatments with proflavine and with sulphathiazole. In all these four subjects the penicillin was effective in greatly decreasing the number of staphylococci, though one subject was carrying only small numbers before the treatment started. In the three subjects that were treated for short periods (seven to ten days) the staphylococci returned after the treatment was discontinued. Chart I shows the successive staphylococcal counts in the left and right nasal cavities of the subject (B) treated with penicillin snuff alone. Chart II shows the fall of the staphylococcal counts in a subject (T) treated for a short period with penicillin, and the subsequent rise a few days after the penicillin was discontinued.

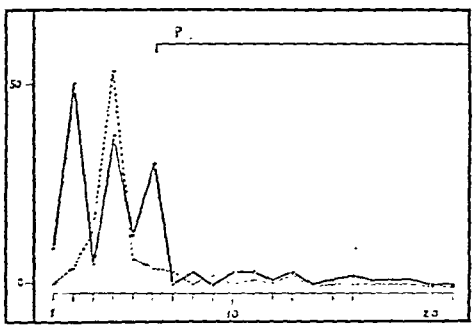

CHART I.—Subject B. Period of treatment with penicillin snuff. (For other details see text.)

In all charts the counts from the left nasal cavity are represented by a continuous line, those from the right nasal cavity by a dotted line. The figures marked along the base line represent successive swabbings, not successive days. In most subjects the routine of swabbing was uninterrupted, so that the interval between any swabbing and the third following it represents seven days.

In these and other counts the ordinates represent the number of staphylococcal colonies counted on the blood-agar plates after forty-eight hours' incubation. Counts of over 100 were recorded as > 100, and are marked as 100 on the charts. Both orange and white colonies are included. The proportions of these colonies often varied widely from one swabbing to another in the same person, and coagulase tests gave positive results with many colonies that showed no trace of orange pigment. Since it was impossible to submit every colony from every plate to a coagulase test the only practicable method was to include them all. We do not think that this has involved any considerable error in the earlier parts of the records or charts. All the subjects selected for these tests were relatively heavy nasal carriers; and it seems

to be uncommon to isolate large numbers of non-pyogenic white staphylococci from the nasal cavities. It is probable that the recording of all staphylococcal colonies has tended to some under-estimation of the reduction following the use of the antiseptic snuffs. In most cases the small numbers of colonies isolated during the later stages of treatment have been of the white variety; but in others a few typical golden colonies have been isolated after an antiseptic snuff has been taken for several days or weeks.

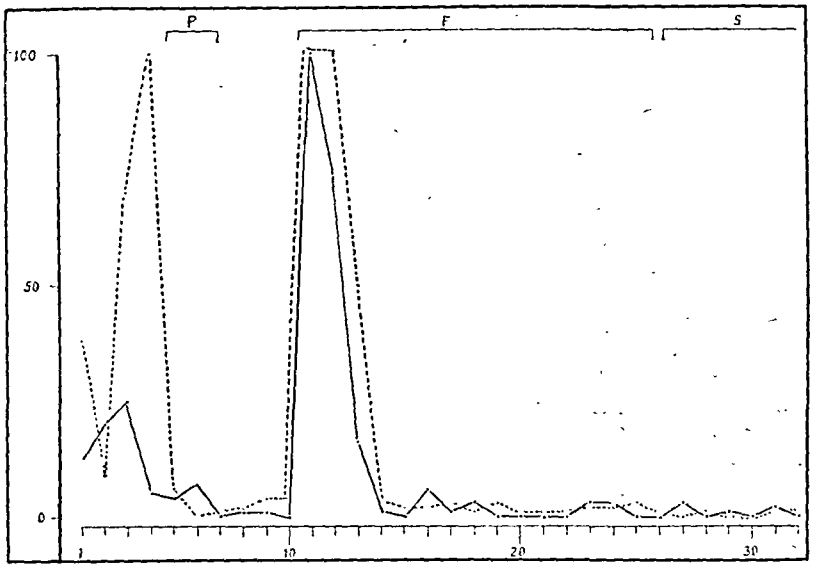

CHART II.—Subject T. P=Period of treatment with penicillin snuff. F=Period of treatment with proflavine snuff. S=Period of treatment with sulphathiazole snuff.

Proflavine Snuff

Nine subjects were treated with proflavine snuff. All of these received other types of snuff either before or after treatment with proflavine. In almost every case there was evidence that the proflavine had an effect on the staphylococcal count, and in some instances the reduction was great; but in some subjects the count, though diminished on the average, showed wide fluctuations. In Chart II it will be noted that Subject T showed a sharp rise in both nasal cavities soon after he began to take proflavine snuff, though previous treatment with penicillin snuff had been followed by a reduction in staphylococci almost to zero. Chart III shows the changes produced by proflavine in a heavy carrier of staphylococci (Subject S). It will be noted that, after wide fluctuations while taking proflavine snuff, the staphylococci were reduced to continuously low figures under the influence of sulphathiazole, the plates on many occasions being sterile. Fig. 3 shows six of the plates obtained from the right and left nasal cavities of Subject S, the first two before any treatment was given, the next two while taking proflavine, and the last two while taking sulphathiazole.

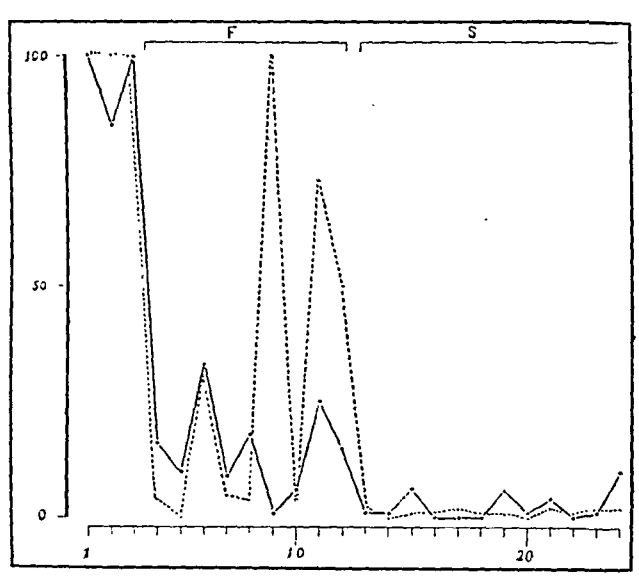

CHART III.—Subject F. F=Period of treatment with proflavine snuff. S=Period of treatment with sulphathiazole snuff.

Sulphathiazole Snuff

Nineteen subjects were treated with sulphathiazole snuff. Ten of these were treated with sulphathiazole alone. The other nine had previously been treated with proflavine or with proflavine and penicillin. The results in general were very promising. Several subjects showed a great reduction in staphylococci; in some these almost disappeared. Two cases have so far proved relatively resistant, though in one of these there was a reduction in one nasal cavity after three days on sulphathiazole and in the other after seventeen days. Chart IV shows the reduction in staphylococci in Subject W under treatment with sulphathiazole, and Chart III shows, in Subject S, the effect of sulphathiazole following proflavine. Fig. 4 shows six of the plates obtained from Subject W, the first three before taking sulphathiazole, the second three afterwards. The plates in the first row were obtained from the right nasal cavity, those in the second row from the left.

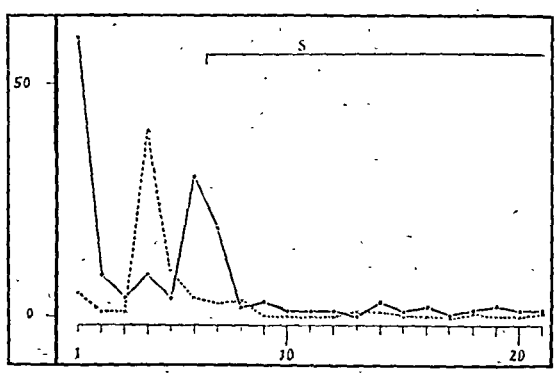

CHART IV.—Subject W. S=Period of treatment with sulphathiazole snuff.

Control Snuff

During an early stage of the investigation three subjects were treated with a control snuff containing only menthol (5%) and lycopodium. None showed any significant change in the nasal flora.

Results with Other Organisms

Staphylococci were not, of course, the only organisms cultivated from the nasal cavities of these 20 persons. In regard to other bacteria a few points are worth noting. Several subjects carried a diphtheroid bacillus which had the morphological appearance of Hoffmann's bacillus but was not further identified. The action of sulphathiazole snuff on this was dramatic. The organism in most cases entirely disappeared shortly after treatment was started. It is quite possible that both penicillin and proflavine would have produced a similar result had similar cases been treated with these snuffs.

A Gram-negative coccus of the *N. pharyngis* type was present in a few subjects. This proved much more resistant than staphylococci both to penicillin and to sulphathiazole. We had no opportunity of testing its resistance to proflavine.

The findings in regard to pneumococci were curious. Not many subjects were nasal carriers of this organism, but in a few cases it appeared while a subject was taking

sulphathiazole snuff, and in some others this snuff failed to rid the nasal cavities of pneumococci that were already present. We have had no opportunity of estimating the effect of penicillin or proflavine on nasal carriers of this organism.

Antiseptic Snuffs in Relation to Colds

There is no evidence that any one of the three antibacterial substances tested has any action on filterable viruses. They would not therefore be expected to have any effect in preventing the acute infectious cold, and no such effect was in evidence. Several subjects developed colds, in most cases very mild, while taking one or other of the snuffs. There was, however, a suggestion that the sulphathiazole, and perhaps the proflavine, had an effect in modifying the course of a cold. One subject with a long history of characteristic colds in previous winters developed a cold that lasted for several weeks, with a relatively copious mucous discharge. Contrary to the experience of earlier years the mucous discharge remained clear throughout, plates from the nasal cavities remained almost sterile, and there were none of the symptoms usually associated with the later stages of a cold when the discharge has become purulent. Another subject, whose nasal cavities were not being swabbed, had a similar experience. A third person, also not included in the bacteriological survey, started to take sulphathiazole snuff on the second day of an acute cold. This cold cleared rapidly, and without the muco-purulent discharge to which the person in question was accustomed. We have had no opportunity of studying the effect of penicillin snuff in similar circumstances.

Discussion

The cases examined in this investigation are far too few to justify any definite conclusion. In normal times we should have hoped to study many more cases before publishing our findings. But the times are not normal, and we are therefore putting these findings on record in the hope that others may be able to test the significance of the results we have obtained, which at the moment are clearly no more than suggestive.

Of the three snuffs we have tried we should not ourselves regard it as worth while to proceed further with proflavine. It has proved less effective than either penicillin or sulphathiazole, and its bright yellow colour is singularly unattractive on the nostrils, the upper lip, or the handkerchief. It seems quite probable that penicillin will prove particularly effective as an antiseptic snuff. We hope later to have an opportunity of putting it to a more adequate test, alone or in combination with sulphathiazole. At the moment we think that the snuff most worth testing is the simple mixture of sulphathiazole and magnesium carbonate, though we suspect that the percentage of sulphathiazole might be increased with advantage. As regards administration, it seems better to avoid using the fingers and so possibly contaminating the snuff in a box. We have dispensed the snuff in small cardboard pill-boxes holding about 1 gramme. An easy method of taking the snuff is to cut or tear a small triangle of paper, and to load one corner with a large pinch of snuff for each nostril. In recent trials we have, quite arbitrarily, instructed the subjects under test to take the snuff six times a day. Used at this rate 1 gramme lasts for three to four

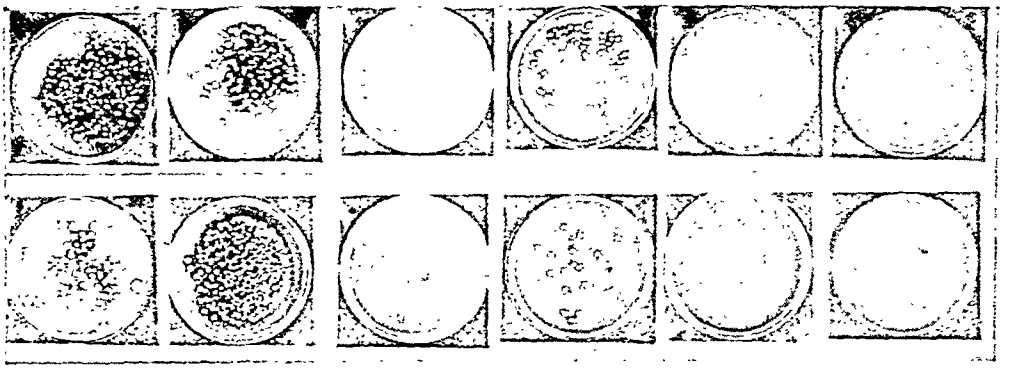

FIG. 3.—*Rows 1 and 2.* Subject S. Six blood-agar plates from right nasal cavity (Row 1) and from left nasal cavity (Row 2). 1 and 2 before taking snuff, 3 and 4 while taking proflavine snuff, 5 and 6 while taking sulphathiazole snuff.

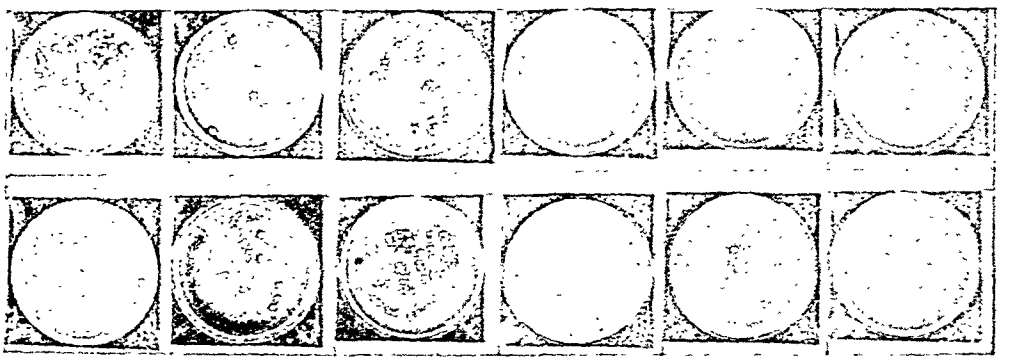

FIG. 4.—*Rows 1 and 2.* Subject W. Six blood-agar plates from right nasal cavity (Row 1) and from left nasal cavity (Row 2): 1 to 3 before taking snuff, 4 to 6 while taking sulphathiazole snuff.

days. This involves the taking of approximately 0.03 gramme of sulphathiazole a day. It is very doubtful whether even this small amount is absorbed. Certainly much of the snuff remains in the nasal mucus, and thence escapes on to the handkerchief. It seems very unlikely that any toxic symptoms would develop from doses of this order, however long they were continued. In view of the apparent failure of sulphathiazole, in the doses employed, to act effectively on pneumococci, against which the drug is known to be active, we think that larger or more frequent doses of snuff, or a higher concentration of the drug, might well be used in future tests.

How far the snuff will be useful as a prophylactic it is impossible to say. It seems reasonable to suppose that, in so far as it can diminish the number of existing pathogens in the nasal cavities, it should help to prevent the multiplication of fresh entrants of the same species in the same situations. As has been noted, an antiseptic snuff has no demonstrable effect on the pre-existing flora of the nasopharynx. It does not follow that it will not reduce the frequency of successful colonization by new entrants through the nasal passages. Some of them may be caught and destroyed on their way through the nose. Moreover, as has been noted above, the snuff certainly gains access to the nasopharynx, and some of it adheres to the mucosa and must therefore lead to a local concentration of the antiseptic. Since inspired bacteria will probably lodge in the same situations, the snuff may be more effective in dealing with these than with the more widely dispersed normal flora. On bacteria breathed in through the mouth it will presumably have little if any effect.

So far as the cure of nasal carriers is concerned, it will be noted that we have not yet succeeded in freeing the nose completely from staphylococci, and have no data as to what happens after the taking of sulphathiazole snuff is stopped. It seems very probable that treatment would have to be continued for a long time to effect any permanent cure, and that, in cases in which organisms are vegetating in deep crypts or in any of the nasal sinuses, an antiseptic snuff would do no more than hold in check the surface colonization.

There is one general criticism that might be made of all our findings with proflavine and penicillin snuffs. It might be argued that the low counts obtained during the period of treatment were due not to any diminution of staphylococci in the nasal cavities but to a reduced growth on our plates resulting from the carrying over of sufficient proflavine or penicillin to produce an inhibitory effect. We do not think that this possibility can be ignored. Swabs were never taken less than two hours after the last administration of snuff, but the active substance may dissolve and diffuse slowly in the nasal mucus. The concentration of the antiseptic in the broth suspension probably varied widely as the result of sampling differences, and may sometimes have been sufficient to inhibit growth. We have no records of swabbings taken several days after proflavine snuff had been discontinued and no other snuff substituted; but Subject T remained almost free from staphylococci for eight days after a short course of penicillin snuff, and it seems very unlikely that an inhibitory concentration could have been present at this period.

The same criticism does not apply to the results obtained with sulphathiazole, since this substance has no inhibitory effect on the growth of staphylococci on plate cultures.

With these reservations we think that the following suggestions are in conformity with the very scanty evidence.

1. An antiseptic snuff containing sulphathiazole or penicillin may lessen the frequency of effective invasion of the nose by bacteria or the invasion of the nasopharynx through the nose. It may therefore prove of use as a prophylactic against bacterial infections of the upper respiratory tract and perhaps against cerebrospinal meningitis, though on the latter point we have no direct evidence apart from the known activity of the sulphanilamide compounds against the meningococcus. The most that can be said at the moment is that the method seems worthy of trial.

2. There is no evidence that it will prevent or cure the common infectious cold. It may favourably affect the course of a cold by preventing secondary bacterial infection.

3. It may perhaps prove effective in curing nasal carriers of staphylococci or in reducing the number of vegetative organisms, so that the carrier becomes less dangerous as a source of infection to others.

4. In view of its action on diphtheroids it seems desirable to test its possible usefulness in the treatment of nasal carriers of diphtheria bacilli.

5. How far it will affect other pathogenic organisms in the nose there is as yet no evidence.

Since none of the antiseptic snuffs we have tested has had any effect on the nasopharyngeal or tonsillar flora we have attempted to influence these flora by the use of tablets containing proflavine or sulphathiazole. These tablets have been gently sucked in the hope of inducing an effective concentration in the throat. Neither has given any demonstrable results, and the aesthetic effects of proflavine tablets have been even less attractive than those of proflavine snuff. We are now investigating the possibility of influencing the nasopharyngeal and tonsillar bacterial flora by the oral insufflation of antiseptic powders; but these trials are as yet in their earliest stages.

Finally we wish to express our thanks to all those who have co-operated with us by taking our snuffs and by submitting to repeated swabbings over many weeks or months.

Malaria in Bengal.—In his report for 1938 Lieut.-Colonel A. C. Chatterji, Director of Public Health, Bengal, states that malaria took away 416,521 lives with a death rate of 8.3 per mille in the year under review, against 372,992 with a death rate of 7.5 per mille in 1937—an increase of 10.6% in the death rate. Malaria accounted for 50.8% of the total fever mortality and for 31.0% of the total provincial mortality. The statistics provide clear and telling evidence of what the future of Bengal villages will be unless adequate measures are devised without loss of time. Malaria is the most important and direct cause of physical unfitness and extensive economic ravages of the population. In Bengal 93% of the people live in villages, but the proportion of malaria between the rural and the urban areas is 99.3 and 0.7 respectively. Altogether 4,273,307 cases of malaria were treated in 1938 in the various hospitals and dispensaries in Bengal, but this number is only a small fraction of the annual malaria incidence in rural and urban areas. It has been estimated that the total incidence is somewhere between 30 and 40 million cases out of a population of 51 millions in this Province of India. Bengal could easily consume 350,000 lb. of quinine every year in the treatment of malaria, but during 1937–8 the amount used was only 112,353 lb. The comprehensive malaria survey of representative areas in different parts of the Province was continued uninterruptedly during the year. The mosquitos collected from the villages surveyed were identified locally by trained assistant epidemiologists in charge of survey parties, and were also sent to the Bengal Malaria Research Laboratory, Calcutta, for checking and confirmation.

DIARRHOEAL DISEASES IN GLASGOW

BY

E. BLOCH, M.A., M.B., Ch.B., D.P.H.

Divisional Medical Officer, Public Health Department, Glasgow

Interest in diarrhoeal disease was intensified following the appointment of a subcommittee on enteritis in infancy by the Preventive Medicine Committee of the Medical Research Council. I am indebted to Dr. A. S. M. Macgregor, a member of the committee, for the suggestion to compile this review of the prevalence of the diarrhoeal diseases in Glasgow, with special reference to non-specific enteritis. The incidence of these diseases is indicated in the following list, which shows the average number of deaths or cases registered annually:

Diarrhoea and enteritis (all ages), 1919-38	422 deaths
Bacillary dysenteries, 1919-38	90 cases
Typhoid, 1925-38	41 "
Paratyphoid, 1925-38	63 "

The specific infections in the above order have shown an average primary fatality of 5, 15, and 5% respectively. As regards the fatality of non-specific diarrhoea, Cooper (1937), studying 300 cases of acute (mild and severe) and chronic gastro-enteritis in a Glasgow children's hospital, recorded a case mortality of 47%. A measure of the morbidity from non-specific enteritis is thus provided, because on an annual average 70% of the deaths from enteritis in patients under 2 years of age occur in hospital.

Age and Sex Distribution

The average age distribution in the non-specific group has been as follows:

	−1	−5	5+	Total
Deaths	293	60	64	422
Percentage	71	14	15	100

Infants are therefore mainly involved. In the specific groups infections of infants are few. Of 908 dysentery patients registered during the past four years, 412 (45%) were under 15 years of age, but only thirty (3.3%) were under 1 year. Similarly, only 2% of paratyphoid and less than 1% of typhoid patients are under 1 year old.

The distribution of the sexes also varies in the different groups. For dysentery it is approximately equal. Among enteric cases, especially paratyphoid, females exceed males —a reversal of sex incidence in years preceding 1914 that has been chiefly attributed to extensive wartime inoculation of males. Infantile digestive diseases, on the other hand, kill 140 males for every 100 females. However, the proportion of infantile mortality in each sex due to digestive disease is approximately the same for males and females—namely, 14 to 15%.

Annual Incidence

The "residual" numbers of the specific infections are occasionally multiplied through agencies which may or may not be recognized. Thus in 1935 forty-one pilgrims imported typhoid; in 1936 paratyphoid notifications numbered 195; and during the period 1935–8 the annual dysentery notifications averaged 227, of which 101 were notifications of infections contracted annually in institutions. Deaths from non-specific diarrhoea show relatively smaller fluctuations. During the past twenty years these have ranged between 279 and 536, excepting 1921, when they numbered 702.

The annual fluctuations in the several diarrhoeal diseases seem mutually unrelated. Between 1919 and 1938 there was increased annual prevalence of one or more of these diseases on thirteen occasions. In eight of these years one or another of the diseases was increased alone; on the remaining five occasions varied associations between the diseases were recorded.

The average of 422 deaths, constituting a death rate of 0.374 per 1,000 living, represents a definite but disappointingly moderate improvement on the rates of 0.843 for the period 1891–1900 and 0.681 for the period 1901–10. Indeed, as long ago as 1909 and 1910 the corresponding rates were 0.130 and 0.161 respectively. On the other hand, the enteric death rate, which was 0.215 in 1891–1900, has now fallen to the low level of 0.010. As annual causes of infantile mortality, digestive diseases continue to be exceeded only by immaturity and respiratory diseases; infrequently infectious disease rises from fourth to third place.

Seasonal Incidence

The following table shows the seasonal incidence of deaths under 1 year from diarrhoea and of their quarterly peak during the decennium 1928–37:

	Quarter				Total
	1st	2nd	3rd	4th	
Deaths	573	603	915	941	3,032
Quarterly peak			7	3	10

Enteric infections, especially typhoid, and non-institutional dysentery also tend to reach a peak in the third quarter, the warmest of the four quarters; but the non-specific group alone reveals the regular occurrence in another quarter of an alternative seasonal peak. Cooper recorded that half his patients had been ill for only a week or less. The high incidence of non-specific diarrhoea in the fourth quarter is therefore not altogether due to the termination in that quarter of illnesses previously contracted.

Graham (in 1936) held that the incidence of infantile mortality from diarrhoea now tended to show a winter instead of a summer peak owing to respiratory infections. The researches of otologists in other parts of the country into the association between otitis and gastro-enteritis lend support to this view, as also to their injunction to mothers to shield their infants from adults suffering from colds or influenza. In Glasgow, too, as described below, an institutional outbreak of presumably virus origin, which caused 7 neonatal deaths among 9 cases during the early part of 1938, was marked by rhinitis at onset, although the terminal phases consisted of enteritis. Nevertheless the seasonal behaviour of the non-specific group can still be described as generally "diarrhoeal" rather than "respiratory" in character. As indicated by the monthly mean shade temperatures, the warmest month of the year is usually July, less frequently August, and deaths from infantile diarrhoea continue to reach their monthly peak, as they did in years preceding 1914, during August or, somewhat less often, in September. Moreover, Macgregor (1933) has pointed out that while bronchopneumonia has an irregular seasonal incidence lobar pneumonia regularly maintains high prevalence during the first four months of the year. As shown above, infantile mortality from diarrhoea is relatively low during the early months of the year. Similarly, Stirk Adams (1937) reported that paracentesis operations for otitis media in a children's out-patient department in Birmingham showed a winter crest and a September trough; whereas, as we have seen, September is a month of high incidence of gastro-enteritis.

Housing Accommodation and Fatal Enteritis

As enteritis is not a notifiable disease epidemiological information regarding cases is generally meagre. During the years 1926–32, however, information regarding size

of house and number of inmates was noted in connexion with the registration of 2,163 deaths from diarrhoea in children under 2 years of age. The opportunity has been taken to compare the housing accommodation of these children with the size of house noted in connexion with a series of births:

	Apartments				Total
	1	2	3	4+	
Births	12	37	29	22	100%
Diarrhoeal deaths under 2 years ..	36	52	10	2	100%

A disproportionate incidence of diarrhoea among the children in the smaller houses is apparent. This analysis also revealed, incidentally, that the housing distribution of births was very similar to the size distribution of all Glasgow houses. In the following table, therefore, one may reasonably compare the percentage of various sizes of houses known to be overcrowded in Glasgow with the percentage of overcrowded houses among the homes of the 2,163 fatal diarrhoea cases:

	Apartments				All Houses
	1	2	3	4+	
Percentage of houses overcrowded:					
[illegible] ..	52	43	18	4	31
[illegible] ..	94	80	47	23	82

A striking degree of overcrowding among the diarrhoea cases is seen when compared with overcrowding existing generally in the city.

To corroborate this finding an effort was made to ascertain the degree of overcrowding among births. Such information is available from health visitors' records regarding midwives' births—i.e., births at which there is no medical attendance. The housing conditions in a series of these births were as shown:

	Apartments				All Houses
	1	2	3	4+	
Midwives' births: size of house .	37	47	12	4	100%
Midwives' births: percentage overcrowded	66	47	33	21	51

A close resemblance is seen between the size distribution of these poor houses and the size distribution, previously tabulated, of the houses of the fatal diarrhoea cases. It is therefore noteworthy that the overcrowding even among the poor homes of the midwives' births falls short of the overcrowding, previously tabulated, in the homes of the diarrhoea cases. The apparent effect of overcrowding is not due, as in the incidence of the infectious fevers, to the frequent occurrence of multiple cases in the same house; for such association of cases, which mainly concerned twins, was very uncommon.

Prevention of Enteritis

In discussing prevention practically all the authorities stress the importance of breast feeding. Still (1933) recorded that 96% of his fatal cases of infantile diarrhoea had occurred among artificially fed children. Graham laid emphasis on breast feeding, hygienic environment, and the maintenance of weight; and ascribed to children in Glasgow under 70% of their normal weight a diarrhoea mortality more than twice as high as among children of normal weight. Cruickshank (1937) specified as the important adverse factors artificial feeding, infancy, unhygienic surroundings, and raised internal or external temperatures. It is of interest to note that Ebbs (1937) also stressed the importance of breast feeding in his discussion of post-mortem examination of 880 children, 80% of whom had died under 2 years of age from all types of medical and surgical conditions. Of these children under 2 years old 238 had suffered from gastro-enteritic symptoms, and 193 of these had had otitis media, while purulent ear material had been found post mortem in 52% of the entire group studied. Only a negligible number of all these children had been breast-fed. On the whole it is accepted that breast feeding (or suitable and careful artificial feeding) and hygienic surroundings are important factors in the prevention of gastro-enteritis as of other infantile diseases. Apart from illness due to any pathogenic bacteria in prepared foods as sold, unsuitable food could obviously result in digestive disorder, while careless feeding could act by conveying infection. In Glasgow, as described above, enteritis deaths are associated with the two unhygienic environmental factors of small size of house and overcrowding of house, and such factors could presumably operate either by impairing vital functions or by facilitating the spread of infections.

Infective Enteritis

Thus both infection and physiological upset appear to play a part among the non-specific diarrhoeas. When cases occur acutely in groups infection is naturally suggested; in other instances digestive derangement seems sufficient explanation. A link between the two types of cases is provided by the work of Blacklock, Guthrie, and Macpherson (1937). They found a sequence of events in infantile gastro-enteritis consisting of impaired gastric secretion, interference with normal acidity, and ascent of coliform organisms to the upper part of the small bowel; and held that these events could be initiated by fever due to an infection as well as by unsuitable feeding, even on occasion by feeding with cows' milk.

Outbreaks of non-specific enteritis outside institutions have not attracted attention in Glasgow. In 1929 one such outbreak was discovered through its association with an epidemic of dysentery. The dysentery epidemic was regarded as comprising 51 persons, although positive specimens were obtained from 35 only. In the non-specific outbreak specimens were examined from 93 persons. At the same time as these two outbreaks were proceeding side by side a morbidity inquiry was being conducted in a neighbouring district, and no cases of infectious diarrhoea were discovered there.

The limited extent of the prevalence of the specific diarrhoeas among even infective cases of diarrhoea thus illustrated increases the importance of the non-specific group and of its study. In a few localities hospital arrangements have been made which diminish possible spread of infection within the institution and at the same time facilitate investigation. For these arrangements the energetic co-operation of the hospital administration is necessary.

Hospital Arrangements

Mitman (1937) and Joe (1937) described their arrangements for the segregation in special wards planned on the "cell" system of all cases of non-specific enteritis, primary or secondary to infectious disease, occurring in two L.C.C. fever hospitals. Special attention was devoted in these wards to the handling of food and to the prevention of cross-infections, whether respiratory or enteral.

The segregation of cases of non-specific enteritis admitted to or sickening in general institutions would also be a valuable procedure. Although open wards, preferably small, might have to be used in some instances, cubicles or compartments are desirable, since a variety of infections may be concerned. The possession of a training qualification in fever by the nursing staff attending

these cases would obviously be an advantage. Epidemiological, clinical, pathological, and therapeutic studies would be facilitated by special wards. Any grouping of cases could be recognized by noting the ward or address of sickening of the cases. The incidence and nature of parenteral complications could be recorded. Cooper, for example, found that 40% of his 300 cases had parenteral affections; of these 122 cases 78 had otitis media, 11 pyuria, and 9 bronchopneumonia. Routine examination of ears, such as was reported by Maizels and Smith (1934), could also be performed, and that preferably by an otologist owing to the difficulties in diagnosis and treatment of ear disease in young children. Chemical and dietetic treatment are aspects attracting investigation even in the present state of knowledge regarding the aetiology of the disease. Chemotherapeutic successes have not yet been reported; but the work of Anderson (1939) on the treatment of measles by sulphanilamide suggested that the latter might have some value in prophylaxis against secondary gastro-enteritis

Enteritis and Otitis

Reference has already been made to the association between enteritis and otitis recorded by Cooper and, to a more striking extent, by Ebbs. Blacklock, Guthrie, and Macpherson found that the purulent exudate seen post mortem in 90% of their gastro-enteritis cases sometimes contained coliform organisms which had presumably spread from vomited material in the nasopharynx. As they also commented, however, other workers continue to submit that otitis may be primary to gastro-enteritis, and, in any case, otitis media figures prominently among parenteral conditions reported to be associated with gastro-enteritis.

The practical implications of this association may cause difficulty to administrators as well as to clinicians. Maizels and Smith reported case mortalities of 31%, 80%, and 50% respectively among their small groups of enteritis cases without ear disease, enteritis cases with surgically untreated ear disease, and enteritis cases treated surgically for ear disease. Such evidence implies that for the routine treatment of infantile gastro-enteritis outdoor medical services would require to be supported by specialist services or ample hospital accommodation.

Since streptococci and pneumococci are said to account for almost two-thirds and one-third respectively of middle-ear infections, Cleminson (1939) suggested the use of sulphapyridine on the first appearance of ear symptoms or signs of otitis in school children. The routine application to infants, however, of even such a chemotherapeutic measure will present a problem in proportion to the difficulty of recognizing the indications for treatment.

A Fatal Neonatal Outbreak

Some points mentioned above are illustrated by a series of related illnesses with terminal enteritis which occurred early in 1938 among the newborn children in the maternity unit of a Glasgow municipal hospital. Although the cases were afebrile infection was obviously at work. Seven of the 9 cases sickened during the first three days of the year, and the remaining 2 within forty-eight hours of each other towards the end of February. The ages at onset were 3 to 7 days. The recurrence of what was apparently the same infection took place despite the closure of the ward to admissions from early in January till mid-February and despite the introduction, on reopening with different nursing attendants, of linen masks for use during the handling of infants. Arrangements had also been made for the sterilization of infants' towels and clothes and for the use of an infant's towel once only.

The infection was obviously respiratory, for the resident medical officers reported that the onset had been marked by rhinitis with clear or purulent discharge. They took nasal swabs from 7 cases and, in connexion with the first group of cases, nose or throat swabs from 28 contacts, including mothers, nurses, and all infant contacts. The following findings were reported:

> Cases: *Staph. aureus*, 2; *Staph. aureus* and diphtheroids, 1; *Staph. albus* and *Strep. viridans*, 1; staphylococci and coliforms, 1. Last two cases: diphtheroids, 1; staphylococci and *M. catarrhalis*, 1.
>
> 18 adult contacts: *Staph. aureus*, 4; *Staph. albus*, 2; staphylococci and streptococci, 11; haemolytic streptococcus, 1.
>
> 10 infant contacts: *Staph aureus*, 4; staphylococci with streptococci and other organisms, 6.

One of the two cases which recovered was also one of the two cases whose nasal swab had yielded *Staph. aureus* in pure culture. Blood culture was attempted in one case, with negative result. One child, born of a syphilitic mother, showed purulent ophthalmia which yielded a staphylococcus, probably *aureus*. Associated infections in the ward were as follows: One case of maternal sepsis in mid-December and another early in January, a case of maternal mastitis early in January, two cases of infantile pemphigus in the second week of December, and an attack of *Staph. aureus* mastitis in an infant a fortnight after his recovery from the outbreak infection.

The terminal phase consisted of enteritis with loose or green stools and, in two instances, the appearance of blood and mucus. Death occurred on the second to the seventh day of illness and the enteritis had appeared one to four days after the onset. Stools were reported negative for staphylococci and streptococci as well as for dysentery and enteric. Similar cases occurring sporadically under different circumstances could understandably present themselves as clinical cases of acute primary enteritis. In the early group the only clinical features reported besides rhinitis and enteritis were loss of weight and, in one case, cyanosis. The last two cases were both fatal. One of these showed oedema of the face and scalp; the other showed hard swelling of the face and scalp, ophthalmia, and attacks of cyanosis with shallow respirations.

The infective agent was not identified nor was its source recognized. Necropsies were performed, however, in 4 of the 7 fatal cases, including the last 2, by the pathologist of Stobhill Hospital, Dr. F. E. Reynolds, and the deaths were ascribed to infection by a virus. Signs of severe toxaemia or of septicaemia were found post mortem. At one necropsy the findings included acute encephalitis and lateral ventricular haemorrhages; at two others haemorrhages of considerable size in various situations, including the peritoneal cavity, were recorded. In the remaining necropsy (Case No. 8) the diagnosis of virus infection was largely based on the clinical history and the epidemic context. Abstracts from the pathologist's reports are given hereunder.

Case No. 5.—No congenital abnormalities: peritoneum covering the structures in upper part of abdomen smeared with blood: lungs deeply congested; about the middle of small intestine, over a distance of 10 cm., mucous membrane haemorrhagic with haemorrhage into lumen, and below this flakes of blood clot mixed with the mucus-like contents of bowel; haemorrhage of some size into right adrenal gland; other organs, including brain, congested. Diagnosis: acute and severe toxaemia. Microscopical examination confirmed the above data.

Case No. 6.—No congenital abnormalities; blood vessels on the surface of the brain and those within its substance engorged; considerable subdural haemorrhage; lateral ventricles filled with dark blood clot: thoracic and abdominal organs deeply congested; Peyer's patches dark red in colour; distal 20 cm. of ileum deeply engorged and a certain amount

of blood in the lumen. Diagnosis: acute encephalitis with consequent haemorrhage into subdural space and into lateral ventricles. Microscopical examination confirmed the diagnosis of acute encephalitis.

Case No. 8.—Well-developed child without congenital abnormalities. Clear dark straw-coloured fluid in pleural cavities and pericardium. Much oedema and many petechial haemorrhages in scalp over vertex and occiput. Pial vessels congested and many petechial haemorrhages in brain substance, including cerebellum. Petechial haemorrhages below visceral pleura on each side and one below visceral pericardium. Several considerable haemorrhages into substance of each kidney. Congestion of lungs, especially bases, and of liver and spleen. Diagnosis: acute septicaemia.

Case No. 9.—Small child, born after 7½ months' pregnancy of mother with a positive blood Wassermann. Considerable haemorrhage into pericardium and into peritoneum. Patches of intense pulmonary congestion into which quite massive haemorrhages had occurred. Liver and spleen almost black from congestion but of average size. Congestion of kidneys, bladder, alimentary tract, and adrenal glands. Considerable oedema of scalp. Leptomeninges and brain intensely congested and some haemorrhage into leptomeninges. Microscopical examination: Brain—vessels congested but no cellular infiltration of perivascular sheaths; occasional small haemorrhages. Liver—blood sinusoids greatly congested. Lungs—in portions examined, alveoli and small bronchi filled with blood.

Summary

The notifiable diarrhoeal diseases have occasions of increased prevalence but "residual" average dimensions. Non-specific diarrhoea results in considerable relatively constant annual mortality, mainly among infants. Specific diarrhoea cases and enteritis deaths are usually highest in the third quarter. Enteritis deaths are regularly frequent also in the fourth quarter. In a Glasgow series of enteritis deaths nearly nine-tenths of the homes were small and four-fifths were overcrowded. The aetiological significance of these seasonal and environmental factors is discussed. Reference is also made to the advantage of segregating hospital cases of non-specific gastro-enteritis and to the practical implications of the recognized frequency of association in infants between enteritis and otitis.

In a winter outbreak of neonatal infections in a Glasgow institution 7 of 9 cases ended fatally after an afebrile illness characterized by rhinitis at onset, loss of weight, and terminal enteritis. The bacteriological findings in the noses or throats of cases and infant and adult contacts are reported. Four cases went to necropsy, and infection was ascribed to an unidentified virus. Abstracts of the pathologist's reports are given.

O. M. Stout and R. J. Kositchek (*Arch. Derm. Syph.*, 1940, **42**, 803) report their observations on fifty-eight patients in whom pruritus was an outstanding symptom and who were treated at first with subcutaneous and later intravenous injections of 50 c.cm. of a 50% solution of dextrose. They found that the injections were of value in treatment of serum sickness, of temporary but often prolonged value in certain kinds of pruritus, and useless for pruritus in dermatitis venenata, senile pruritus, and infectious eczematoid dermatitis.

THE PROPHYLAXIS OF THROAT INFECTION

BY

R. ERNEST KING, B.Sc., M.B., Ch.B.

Surgeon Lieutenant, R.N.V.R.

At this time of the year there is always a sharp rise in the incidence of infections of the upper respiratory tract. This winter the conditions of overcrowding and poor ventilation which prevail in public air-raid shelters will undoubtedly prove to be another important factor in the aetiology of these diseases. Various remedies to solve the shelter problem, such as the use of aerosols to diminish air-borne bacteria, are being investigated, but it is unlikely that these will be in operation before the winter is far advanced. In the meantime some simple method of prophylaxis which can be easily applied to large numbers of people is urgently required.

The Case for Nasopharyngeal Hygiene

The throat and nasopharynx form a natural reservoir and breeding ground for many varieties of pathogenic organisms, their dissemination into the atmosphere taking place by means of the buccal spray. A recent Ministry of Health memorandum (Straker, Hill, and Lovell, 1939) on the bacteria of the nasopharynx has shown that the carrier rate of throat-borne infections is astonishingly high, up to 20% of throat swabs yielding cultures of *Strept. haemolyticus* and 20 to 60% yielding pneumococci. *Haemophilus influenzae* showed a constant carrier rate in the nasopharynx of 60 to 65%. It has also been proved that during most of the large influenza epidemics of recent years the causal virus could be isolated from throat garglings.

Local treatment of the throat and nasopharynx has been regarded with a great deal of reserve since the last war, due largely to the conflicting results obtained in attempts to eliminate the meningococcus carrier. But in view of the pathogens which inhabit the throat in both health and disease there must still be a place in prophylaxis and therapeutics for one method of local treatment—the antiseptic throat spray. For whereas the limit of effective action of the gargle is somewhere between the pillars of the fauces, the throat spray, which projects droplets of fluid direct into the throat, brings the antiseptic into contact with the pharyngeal mucosa.

The following investigation was carried out in a large naval training establishment during the 1939–40 epidemic of influenzal nasopharyngo-tracheitis with the object of estimating the prophylactic value of the antiseptic throat spray. A solution of sodium hypochlorite (15 to 20%) was chosen as the antiseptic because it combines a powerful bactericidal action with a strong oxidizing and deodorant quality.

Procedure

Two groups each of fifty naval ratings were selected from those joining the establishment for the first time. Care was taken to ensure that these two groups should live under identical conditions in the same part of the establishment and that they should perform similar duties. From the day of joining the establishment one of these groups was subjected to a daily prophylactic routine, this being omitted in the case of the other group. The routine adopted was as follows: Each morning at 6.45, immediately after assembly, the group chosen for treatment was subjected to a throat spray of 15 to 20% sodium hypochlorite solution. The instrument used for producing the spray was a portable pressure atomizer. This consists of a hand-pressure pump fitted with a spray nozzle and

made of chromium-finished metal. During use pressure in the body of the instrument was raised by means of the hand pump, the spray being controlled by a stopcock at the base. The spray was projected direct into the throat and the fluid accumulating from this was enough for a final gargle. It was found that the treatment could be carried out on a class of fifty ratings in six to seven minutes. This routine was continued daily until the time of their departure from the establishment some five weeks after joining. During these weeks any rating of either class who reported to the medical department with any complaint whatever was seen by me and his condition noted.

	Untreated Group	Treated Group
Number admitted to hospital	13 (26%)	6 (12%)
Complaint	Acute sore throat, 11; common cold, 2	Cerebrospinal meningitis, 1*; acute sore throat, 3; common cold, 2
Number attending for daily treatment	23 (46%)	12 (24%)
Complaint	Sore throat, 13; common cold, 4; suppurative otitis media, 1	Sore throat, 6; common cold, 6

* This case of cerebrospinal meningitis developed on the second day after the entry of the rating to the establishment.

By "acute sore throat" is meant acute streptococcal tonsillitis and pharyngitis, together with marked constitutional symptoms so typical of the 1939–40 epidemic. By "sore throat" is meant a subacute infection of fauces and pharynx, and "common cold" indicates acute coryza with slight constitutional symptoms but little or no throat infection.

Conclusions

The results of this investigation, which are shown in the preceding table, demonstrate clearly that during the five weeks that these two groups remained under observation the incidence of sickness occurring in the treated group was greatly diminished. The total number of patients requiring to be admitted to hospital during this period, as well as those receiving ambulant treatment, was reduced by half in the treated as compared with the untreated group. This diminution was entirely due to the decreased incidence of acute and subacute throat infections, the incidence of "common cold" being more or less equal in both groups. Clinically it was observed that the acute throat infection occurring in members of the treated group was similar in severity and in duration of illness to that occurring in members of the untreated group. This suggests that the use of prophylactic treatment failed to attenuate the virulence of the infecting organisms in those cases in which they were not primarily destroyed.

The favourable results obtained in this small experiment indicate that the use of an antiseptic throat spray is a justifiable prophylactic measure against such common winter ailments as acute and subacute streptococcal throat infections and influenza.

Summary

The incidence of pathogenic organisms in the throat is briefly discussed and a method of destroying them by antiseptic throat spray is suggested.

A comparison is given of the incidence of infection in two groups each of fifty naval ratings during a period of five weeks, only one group receiving prophylactic treatment.

The prophylaxis consisted of a throat spray and gargle of 15 to 20% sodium hypochlorite solution each morning on rising for five weeks.

It is shown that the incidence of acute and subacute throat infection in the group receiving prophylactic treatment was greatly diminished.

The severity of the clinical condition once it has developed is unaffected by the previous prophylactic treatment.

I am indebted to Surgeon Captain J. Bruce Ronaldson, R.N.V.R., for his co-operation and to Sick Berth Attendant J. L. Patterson for his assistance. My thanks are also due to Mr. H. C. Edgell of Milton Proprietary, Ltd., for the supply of sodium hypochlorite solution and pressure atomizers.

MECHANISM OF PARTIAL REBREATHING IN ANAESTHESIA

BY

R. L. WYNNE, M.B., M.R.C.S., D.A.
Anaesthetist, Birkenhead General Hospital

With modern apparatus for gas-and-oxygen anaesthesia rebreathing is always provided for by the use of a bag, and CO_2 is eliminated by absorption or by the use of an expiratory valve. The former method (absorption) will not be considered here. The latter, by which a portion of each expiration is retained and a portion released into the atmosphere, constitutes "partial rebreathing," and may be applied to continuous or to intermittent flow. In either case the ultimate justification for partial rebreathing lies in the fact that the non-alveolar upper air-passages add warmth and moisture to the gases they contain, but take no part in real ventilation, so that any procedure which conserves their contents while still permitting adequate ventilation at a lower level is rational and beneficial, the more so that increased lung expansion and oxygenation are thereby occasioned.

Some Important Factors

In examining the mechanism of this process, consideration must be given to the following factors: (1) the "spirometer gradient"; (2) the total minute-flow of the anaesthetic mixture; (3) the total minute ventilation of the respiration and its relation to the gas flow; (4) the metabolic needs of the patient.

The "spirometer gradient" depends on the fact that the CO_2 content of the expired air increases until about 800 c.cm. has been released, the content then reaching a maximal value, which is taken as representing the common concentration of CO_2 in the alveolar field. The actual form of this gradient is shown in Fig. 1, and is of import-

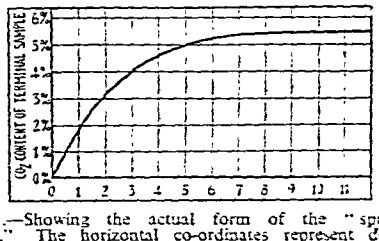

FIG. 1.—Showing the actual form of the "spirometer gradient." The horizontal co-ordinates represent depth of expiration in hundreds of c.cm.

ance in the mechanism of rebreathing. It will of course vary slightly in different individuals or from time to time in the same individual. The curve here given is based on Haldane's figures.

The extent of rebreathing is determined by the relation between respiration and gas flow. Thus if respiration amounted to 12 litres per minute, and in the meantime

6 litres of new gas had flowed into the apparatus, the difference—6 litres, or 50%—would have been rebreathed.

The effects of the process are indicated in Figs. 2–5. In Fig. 2 it is supposed that a tidal respiration of 400 c.cm. is modified by "50% rebreathing." The point

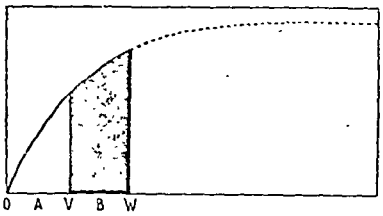

FIG. 2.—Schematic representation of 400 c.cm. tidal respiration, with 50% rebreathing. The white area enclosed under the curve at A represents the amount of CO_2 rebreathed, and the black area at B the amount of CO_2 exhaled into the atmosphere.

during expiration at which the valve opens is indicated by "V," and the end of expiration by "W." It will be seen that the upper dilute portion of the expiration, O–V, is retained for rebreathing, while the lower more concentrated portion, V–W, is released through the valve. The effective release of CO_2 is in this case performed by 200 c.cm. of deeper expiratory air. Figs. 3 and 4 make clear

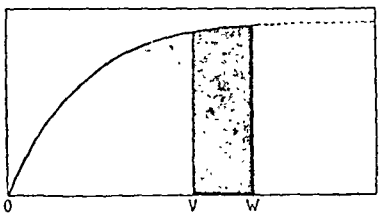

FIG. 3.—The effect of an increase in tidal respiration to 800 c.cm., with a fixed continuous flow. There is a large increase in the amount of CO_2 rebreathed, and a relatively small increase in that exhaled into the atmosphere.

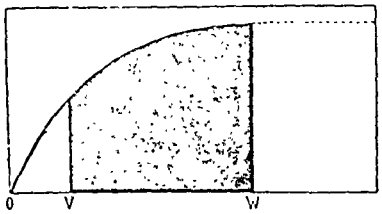

FIG. 4.—The effect of the same increase with intermittent flow. The amount rebreathed is constant, and the whole increase of tidal respiration carries CO_2 in much greater amount into the atmosphere.

the essential difference between the mechanism in continuous flow, where the volume of effective release, V–W, though movable, remains constant for a given frequency of respiration, and in intermittent flow, where it is the volume rebreathed, O–V, which remains constant.

The patient's metabolic needs must now be considered. As Guedel (1937) has pointed out, many factors tend to modify the oxygen intake and CO_2 output of the patient who reaches the operating table; but in hospital conditions these will be depressed to a minimum by resting conditions and premedication. Gesell (1939) gives for an average adult B.M.R. in the lying position an oxygen intake of 234 c.cm. per minute, representing 1.14 calories, so that if a respiratory quotient of near 1 be assumed, 250 c.cm. per minute can be regarded as a likely *maximum* for CO_2 elimination in the average adult. Now, however deeply respiration is maintained, this cannot be expired at a concentration greater than that of alveolar air, which is 5 to 6%; and if, for example, it is released in the form of a 5% mixture the real ventilation will have to be in the neighbourhood of 5 litres a minute. The volume released into the atmosphere must needs be nearly equal to the flow of gas into the apparatus; and these figures correspond with clinical experience that in using continuous-flow apparatus a gas flow of some 6 to 7 litres a minute generally ensures good results, but that if the flow is restricted much under 5 litres the patient develops signs of CO_2 accumulation.

The "Critical Flow"

This "critical flow," which if diminished is followed by CO_2 accumulation, is exactly determined in each individual by (1) his rate of elimination of CO_2, and (2) the percentage of CO_2 normal for his individual alveolar system. Since in Figs. 2, 3, and 5 the "effective release," V–W, remains constant, respiratory adjustment will take place by a shift of this fixed line to right or left, and a consequent alteration in the height of the black column and the area contained by it, which represents CO_2. It will be seen that there is a limit to the effectiveness of hyperpnoea, indicated in Fig. 5, and if this "limiting

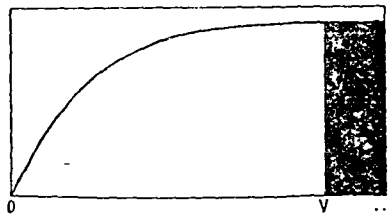

FIG. 5.—The "limiting value" with continuous flow. No matter how far the curve is produced to the right (by increased depth of respiration) the black area will not increase.

value" of CO_2 release does not account for all the CO_2 liberated in the alveoli the latter will begin to accumulate. Altered frequency of respiration will accomplish nothing, for the volume V–W is equal to the gas flow divided by the frequency, and will become contracted in inverse proportion to the latter, so that no increase in total elimination over a given period will result.

It will be seen that in partial rebreathing with continuous flow the natural respiratory mechanism is considerably modified by the apparatus to which the patient is connected. The ventilation per minute is arbitrarily limited, and the patient's efforts to modify it alter only the *depth* within the respiratory system at which the fixed ventilation takes place, this depth being *mechanically* limited by the maximum tidal exchange of which he is capable, but *physiologically* limited by the depth (about 800 c.cm.) of respiration after which no further increase in CO_2 percentage occurs.

This is in contrast to conditions prevailing in normal repiration or open anaesthesia, where increased respiratory movements at once increase both the depth and volume of real ventilation. It is also in contrast to the means of rebreathing employed in the intermittent-flow machine (for example, McKesson), in which it is the volume to be rebreathed which is arbitrarily set beforehand, and in which hyperpnoea causes an immediate increase in real ventilation, by drawing on an increased flow of gases. In this latter method the design of the bag is important. With continuous flow it matters not for this purpose how large the bag is, for it will expand sufficiently to operate the valve, and thereafter contract only by the amount of rebreathing determined by the relation between respiration and gas flow. In an intermittent-flow machine working without pressure, however, the patient must empty the bag entirely before he can draw on new gas; and provision must therefore be made for limiting its capacity to a known small amount.

Conclusions

Partial rebreathing is justified in so far as it promotes lung-expansion and oxygenation, and retains the warmth and moisture of the upper respiratory contents while permitting adequate ventilation below.

Its extent is modified in the continuous-flow machine by adjustment of the gas flow, and in the intermittent-flow machine by adjustment of the bag capacity.

The patient's effective alveolar ventilation is controlled, as always, by the alveolar CO_2 concentration.

For continuous-flow machines there is a "critical flow" in the neighbourhood of 5 litres per minute for each individual, which if diminished will lead to CO_2 accumulation, but which if exceeded allows equilibrium to be attained.

Continuous flow is dangerous with a flow below the critical level; intermittent flow is dangerous with an unlimited bag capacity.

LAURENCE-MOON-BIEDL SYNDROME, WITH TETANY

BY

FRANCIS D'ABREU, M.Ch., F.R.C.S.
Major, R.A.M.C.

AND

DAVID FERRIMAN, D.M., M.R.C.P.

The following interesting case, considered to be an example of the Laurence-Moon-Biedl syndrome without polydactyly or mental deficiency, seems to merit publication.

Case History

A young woman aged 25 was admitted to Westminster Hospital in October, 1938. Her immediate complaint was of pain in the left loin that had been present for a week. The features which had actually led to her admission were blindness—present from birth—and attacks of tetany. These attacks dated from the age of 10, and had been occasional until nine months before. From that time they became more frequent, and just before her admission were occurring about twice a week. During the last two years she had also complained of pain in her back, for which she had been given a spinal jacket at another hospital. A report from this hospital stated that radiographs of the bones seemed normal. There was no history of vomiting. She had at one time been rather fat: with the onset of tetany she had gone to the opposite extreme, but recently she had returned more or less to normal. Her menstruation had been irregular and infrequent from the onset at 11, but the intervals had steadily increased from the minimum of three months, her last period having taken place four years ago. A further sixteen sibs of this patient had been born, of whom only five are now alive. Four of these sixteen were blind at birth, and only one is living. No abnormal fatness, tetany, or mental deficiency had affected any sibs: a sister with unaffected vision, however, had had six toes on either foot—she died early in life. The mother suffered from diabetes, but otherwise she and the father were healthy; they were unrelated.

A number of typical attacks of tetany with carpo-pedal and facial spasm were observed during the patient's stay in hospital. Chvostek's and Trousseau's signs were positive and could be elicited at any time with ease. Her veins were abnormally irritable; none were visible and no blood could be obtained from any of them, not even after cutting down and exposing them, as they went into intense spasm on the prick of the needle. Eventually blood had to be taken by needle from the femoral artery. The nursing staff had not observed any hyperpnoea. Mr. E. F. King examined the patient's eyes, and important findings are as follows: No light perception; pupils inactive to light; posterior cortical complicated cataracts; both retinae show gross primary degeneration with secondary narrowing of the retinal vessels and optic atrophy. "The picture is somewhat like retinitis pigmentosa, though the size and distribution of the pigmentation are not typical, and of course the history of blindness from birth is atypical." The patient was plump but hardly obese; polydactyly was not present. Her breast development and hair distribution were healthy. She appeared quite intelligent. She was tender in both loins and the urine contained albumin.

Special investigations gave results as follows: Serum calcium 9.2 mg., 10.9 mg., and 9.3 mg. per 100 c.cm.; plasma phosphorus 3.8 mg. and 4.2 mg. per 100 c.cm.; serum phosphatase 11 units; alkali reserve 61 c.cm. carbon dioxide %; blood urea 19 mg. per 100 c.cm. Radiographs of lumbar and dorsal spine disclosed nothing abnormal. The urine contained *B. coli*. An intravenous pyelography failed to reveal abnormality. The basal metabolic rate was −14%. The glucose-tolerance curve was normal, and the Wassermann and Kahn reactions were negative. A full blood count was normal.

The patient was put on three-quarters of an ounce of calcium lactate and 50,000 international units of vitamin D daily. Dr. G. A. Tuck, her medical practitioner, reports that she is greatly improved and that she has had only one attack of tetany in the last three months. It is interesting that her veins are now readily visible.

Discussion

Both the cause of the tetany and the diagnosis of the case are obscure. The investigations appear to rule out any of the accepted causes of tetany. An explanation was somewhat tentatively advanced by Dr. Raymond Greene. It runs as follows:

"Obesity has been present at one time: this and the amenorrhoea might be of pituitary or hypothalamic origin. A parathyrotrophic hormone is to be found in the pituitary. The increasing intervals between the periods and the variation in the obesity suggest an alteration in the level of pituitary secretion over a period of years. If the secretion of the parathyrotrophic hormone at some earlier time was high but has now sunk to normal levels (as indicated by present normal blood calcium and phosphorus figures) then it is possible that the tetany of this case is a consequence of the body's failure to adapt itself, as yet, to the relatively low calcium level."

The result of treatment with calcium and vitamin D supports an explanation along some such lines. No other hypothesis has been suggested.

We believe this case to be an example of the Laurence-Moon-Biedl syndrome. Admittedly polydactyly and mental deficiency are absent, but this has been so in other accepted cases. The absence of obesity *is* unusual, though Cockayne and co-workers (1935, 1939) have found records of this in a few cases; further, obesity was at one time present in this case. The menstrual disturbance supports the diagnosis. The obesity and amenorrhoea of the syndrome have usually been taken to indicate a pituitary or hypothalamic lesion. A lesion of such a nature in this case is further suggested by the tetany. Cockayne, Krestin, and Sorsby (1935) say, in connexion with atypical retinitis pigmentosa in this disease, that "typical retinitis pigmentosa would appear to be the exception." The affection of four other sibs, the parents being unaffected, is suggestive of a recessive mode of inheritance, and this is consistent with what is known of the syndrome (Cockayne and co-workers, 1935, 1939). The appearance of poly-

dactyly in another otherwise unaffected sib is significant and also rather typical (Cockayne and co-workers, 1935, 1939).

No other diagnosis has been advanced.

This case is described by the courtesy of Mr. G. T. Mullally, under whose care it was.

Clinical Memoranda

A Suspected Case of Chronic Meningococcal Septicaemia

Details of the following case are submitted because it is felt that the diagnosis of chronic meningococcal septicaemia is easy if the condition is borne in mind, and because, with the present high incidence of cerebrospinal fever, there must be many cases which pass unrecognized.

Chronic meningococcal septicaemia was originally reported by Saloman (1902), and it has since been seen in increasing numbers on the Continent and in America. The only case reported in England since Stewart-Wallace (1936) recorded 3 from the London Hospital was that by Dimson (1938), which was treated with sulphapyridine. Stott and Copeman (1940) analysed seventeen cases out of a total of twenty-seven which they had seen among members of the B.E.F. in France. Stott (private communication) saw a considerable number more after the paper had gone to press, but had not seen any in this country. As pointed out by Appelbaum (1939), the condition occurs among both sexes and in all age groups. It is common before and after an epidemic of cerebrospinal fever, and is often ushered in by an acute tonsillitis or other upper respiratory infection.

CASE HISTORY

The patient was a previously healthy soldier aged 24 who had never been out of the country. He was admitted to hospital on September 5, complaining of sore throat and fever. His temperature that night was 103° and his pulse 108; his throat was red and injected. A throat swab yielded an abundant growth of haemolytic streptococci. By the following day his temperature was normal, and he made an uninterrupted recovery; so much so that he was due for discharge from hospital on September 12, when he had his first bout of fever.

On the evening of the 12th he retired to bed with a temperature of 103°, sweated, felt cold, and said that his head ached. On the following morning his temperature was normal, but a crop of spots was noticed on his legs, arms, and back. These spots were hard, raised, macular, and tender, and recurred in crops; they resembled slightly those seen in erythema nodosum. His temperature rose again on the evening of the 13th, but by the following morning was again normal: the cutaneous eruption had faded, leaving slight brownish pigmentation. On the 15th, 18th, 21st, 25th, and 26th his evening temperature rose to 102–104°, his pulse rate rarely reached 100 and never exceeded 120. A fresh crop of spots appeared with each bout of pyrexia and faded in about thirty-six hours. At no time did the patient feel ill, he was not clinically anaemic, and the spleen was not palpable.

A radiograph of the sinuses on September 11 revealed slight clouding of both antra, suggesting catarrh. A radiograph of the chest on September 20 showed the lungs to be clear. Blood cultures on the 21st, 25th, and 27th were sterile. Examination of a film of blood on the 25th revealed no malarial parasites, and the blood Wassermann reaction was negative.

A full course of sulphapyridine was begun on the 27th, and thereafter the temperature remained subnormal. The patient was discharged from hospital on October 8.

This case is interesting from the point of view of the diagnosis. Chronic meningococcal septicaemia is probably commoner than is supposed, and may become increasingly so because of the high incidence of cerebrospinal fever which has been maintained throughout the year. Its clinical recognition should be simple, according to Stott and Copeman (1940): pyrexia, associated with a relatively slow pulse, a cutaneous eruption which may be pleomorphic but is often similar to that of erythema nodosum, and the absence of malaise, wasting, and anaemia are the main points which they stress. Blood cultures in the above case were negative, and in Stott and Copeman's series there were only six positives. Cerebrospinal fluid is always normal in the uncomplicated cases. Response to sulphapyridine is immediate.

The focus of infection is as yet unknown, but it is possible that sinus infection plays a part. Rolleston (1919) quoted a case with antral infection, but pus obtained by puncture did not yield meningococci. In my case the antra were cloudy, but, as this was attributed to catarrh, puncture was not carried out.

I am indebted to Dr. L. C. Martin, physician to the hospital, for permission to publish the details of this case, which was under his care, and for help in preparation. Also to Colonel A. W. Stott, R.A.M.C., consulting physician to the Forces, for help in the final diagnosis of the case.

A. GRAHAM PORTER, B.A., M.B., B.Ch.,
House-physician, Emergency Hospital, Cambridge.

The Pectoralis Major for Intramuscular Injections

The buttock, though universally recommended, has many drawbacks as a recipient of intramuscular injections. The fat-screen is variable and often massive; the marks and guides are indefinite; there are large veins, arteries, and nerves within reach (I have more than once known the sciatic nerve injected); if tenderness develops from the injection, walking, standing, sitting, and even lying down are painful. The region is apt to have unaesthetic associations, there is often hesitation in giving sufficient exposure, and falls of drapery may be embarrassing. These considerations many years ago impelled me to seek another site, and the edge of the pectoralis major was chosen; it has been used almost exclusively since, and no drawbacks have been found.

The doctor stands at the side of the patient, preferably the left. Men patients remove their shirt from that shoulder; women may usually retain their underclothes if these have fairly large armholes. The patient raises the arm sideways to a right angle; resting the hand on the doctor's right shoulder often gives confidence, and the slight pull on the arm brings the edge of the pectoralis major into prominence. After cleaning the skin with antiseptic the doctor's left thumb is placed on the axillary side of the muscle and his forefinger in front of it; the edge of the muscle is thus grasped, and a little pressure will make it tense and facilitate the puncture. The needle is inserted parallel with the shoulders and with the anterior surface of the muscle, between the thumb and finger, which serve as guides.

It is easy to direct the needle into the muscle with precision, and its penetration can be felt. There is little fat in the way, there are no large vessels or nerves in the neighbourhood, and it is not very sensitive. Ten c.cm. is accommodated with ease, 20 c.cm. is well tolerated, and absorption is rapid. The same site can be used repeatedly, though it is easy to choose different parts of the muscle. Bismuth and other opaque injections can easily be observed with *x* rays, and their absorption so watched. Pain or tenderness is rare; even with irritating materials they appear to be less frequent than in the buttock, possibly because extra-muscular injection is less often achieved. If tenderness should develop the left arm can usually be rested or even placed in a sling.

To stand behind all diets

¼ lb. and 1 lb. cartons

In the task of nourishing and protecting the nation, Farex can play a valuable part Farex embodies in a single digestible food protective vitamins and minerals which otherwise could only be secured in an expertly chosen and varied diet Farex is composed of wheat-flour, wheat-germ, oatmeal and maize, with *added* minerals and vitamins A, B and D. As befits a 'staple food,' Farex provides an abundance of carbohydrate; but the high percentage of protein (15%) and the presence of iron, calcium and phosphorus, and vitamins A, B and D, lift it right away from the usual run of 'health cereals.' As a weaning and invalid food Farex has been used successfully for years But now, when national good health is a national armament, it cannot be too strongly emphasised that Farex is equally valuable as a daily nutritional safeguard to stand behind *all* diets, for all ages and conditions of people. Farex is ready-cooked, prepared in a few moments, and can be flavoured to personal taste In emergency, Farex alone will maintain the nutrition of the individual longer than any other single food available

Easing the burden of life-long treatment for Pernicious Anaemia

Examen Liver Extract provides the physician with the means not only of quickly restoring the patient's normal blood picture, but of securing the *most effective maintenance treatment with the minimum of discomfort and expense to the patient.* Each 2 cc. of Examen is derived from 100 gm. of fresh liver. Such concentration of the erythrocyte maturing factor maintains normal hæmopoiesis with small, widely spaced doses, e.g. 2 cc. every 3 to 5 weeks. The exceptional purity of Examen and its freedom from protein render injection painless and ensure absence of undesirable reactions.

A—Ret.—*Reticulocytes (per cent. R.B.C.)*
B—R.B.C.—*Red blood corpuscles (millions per cmm.)*
C—Hb.—*Haemoglobin (per cent)*

The graph (an example of an actual case) indicates how Examen gives the required reticulocyte response, followed by a rapid regeneration of red blood corpuscles and the restoration of the hæmoglobin level.

Reviews

THE KIDNEY IN CHRONIC BRIGHT'S DISEASE

Architecture of the Kidney in Chronic Bright's Disease. By Jean Oliver. (Pp. 257; illustrated. $10.00. New York: Paul B. Hoeber.

In a remarkable book Dr. Jean Oliver here states the results of his continued pathological researches on chronic disease of the kidney, which were begun in collaboration with Dr. T. Addis's clinical work in their attempt to elucidate the renal lesion of Bright's disease and correlate the bedside and post-mortem findings. The great advance he has made in dealing with the problems involved is in utilizing two methods which allow demonstration of the tubules of the kidney in three-dimensional form. The first is in tearing out and isolating the tubule from surrounding tissues that have been previously macerated by a reagent; concentrated hydrochloric acid at room temperature for one or two days after fixation with 10% formalin was used. The second procedure is reconstruction in plastic wax from serial sections. The kidneys used for these studies are from the material of the earlier investigation, so that already much clinical and pathological data had been accumulated, and the present work is an objective description of the results.

The architectural unit of the kidney is the nephron, an elemental structure that includes the glomerulus and tubule to the point of its entrance into the common collecting system. The simplest modifications are increase or decrease in size, and these variations, hypertrophied and atrophied nephrons, occur in disease. In the atrophic tubule there is decrease in tubule diameter associated with loss of complexity, straightening, and shortening. The hypertrophied tubule shows increase in diameter and in its length, the result being an increase to as much as ten times the volume of a normal nephron. It would be difficult to deny the likelihood that the functional ability of the atrophied tubule is decreased, but more exact knowledge is needed before drawing conclusions as to the significance of the hypertrophied nephrons as regards function. It is shown that it is principally the terminal part of the proximal convolution which is affected. The blood supply to this part has largely been shunted straight into the efferent vessel by enlargement of Ludwig's vessel without having undergone change by passage through the glomerular mechanism, for in these hypertrophied tubules the glomerulus is disproportionately small. Moreover, in many instances of chronic Bright's disease there is obliteration of the glomerulus without their necessarily being destruction of the whole nephron, and it is probable that these aglomerular nephrons are capable of function. There are certain new elements, portions of tubules forming completely closed vesicles, but no new-formed tubules or bud-like outgrowths could be demonstrated.

Discussing the pathology of chronic Bright's disease Dr. Oliver discounts the effect of glomerular destruction in causing tubular atrophy. Regressive changes of the nephron follow sclerosis of the arteries of the kidney: but these changes may be considered a part of the life-history of the organ, the evidences of senile involution. On top of this, interstitial inflammatory reaction appears to be a considerable factor in the production of alterations in the architecture of the kidney in Bright's disease. In some instances, when death occurs early in the course of the disease, the inflammatory processes in glomeruli and interstitial tissue may be only incipient, and it is easy to understand that such kidneys, if the patient survives, should recover their normal organ structure. In more protracted cases it is possible to group the appearances into two classes which differ fundamentally: in the first group regressive changes take place; in the second, besides the regressive changes of nephron atrophy and hydronephrotic destruction, there are added progressive alterations of hypertrophy and hyperplasia. The author believes that in the regressive form "the renal lesion proceeds uninterruptedly at a level of intensity sufficient at last to preclude the development of progressive and adaptive change. In the adaptive type, though at times the intensity of the renal lesion may be high, there are periods of remission so that vessel new-growth and the changes of hypertrophy and hyperplasia can occur." Following the contraction of inflammatory interstitial tissue, scarring may produce tubular atrophy and at times tubular hydronephrosis.

There appears to be an alteration from the normal predominantly glomerular function towards a condition of increased tubular elimination. This conclusion is formed not only on the demonstration of aglomerular nephrons but also on the blood supply being changed to a more direct tubular supply. Further, the different forms of Bright's disease, whether primarily characterized by glomerular inflammation, amyloid degeneration, or arteriosclerosis, may present kidneys in the final result remarkably similar. Further work on the lines described in Dr. Oliver's book should enable the physician and pathologist to meet with greater understanding each other's problems and to obtain a clearer view of the structure and function of the kidney in chronic Bright's disease.

MODERN DRUGS

Modern Drugs in General Practice. By Ethel Browning, M.D., Ch.B. (Pp. 236. 10s. 6d. net.) London: Edward Arnold and Co.

The rapid increase in the number of powerful therapeutic agents which the labours of the organic chemist have put at the disposal of the medical profession creates a real demand for such a book as Dr. Ethel Browning's *Modern Drugs in General Practice*. Any drug with a powerful therapeutic effect must also be toxic if not used with discrimination, and in these pages the general practitioner will find just the kind of information he requires. Naturally the great triumph of chemotherapy—the sulphonamide group—is given pride of place, and we note two interesting observations under that head. One is the curious liability of sufferers from rheumatic affections to develop two of the rarest and most severe effects of sulphonamide toxicity—agranulocytosis and encephalomyelitis. The other is the point urged in favour of combining treatment by antisera with sulphapyridine in pneumonia—that the bacteriostatic effect of the latter does not have to wait for the specific antibodies to develop before the cure can be completed. Gold therapy is next critically discussed, and the conclusion is reached that active rheumatoid arthritis is the only really satisfactory indication for its employment. (We should have liked to see Forrestier's name in the references on this point.) Then cardiac drugs are considered, including digitalis, which, though by no means a modern drug, has undergone modern developments. Here we are surprised to find no mention of the influence of digitalis on conductivity. Indeed, the whole section on the effects of digitalis and quinidine in auricular fibrillation lacks precision. Coramine and metrazol are dealt with adequately, as are the barbiturates, though not all would agree with the statement that prominal is more effective in grand mal than in petit mal. The arrangement of the chapter on drugs acting on the autonomic nervous system under Dale's classification of cholinergic and adrenergic is admirable: it will be very helpful to those practitioners

whose physiology is of an earlier date and who consequently may find the modern conceptions obscure. The remaining sections deal with such topics as hypnotics, urinary antiseptics, gastro-intestinal remedies, and external applications, including local anaesthetics. The practitioner will find this book an excellent adjunct to his library, and we expect it will reside on his desk rather than on his bookshelf.

CRIME BETWEEN THE WARS

Social Aspects of Crime in England between the Wars. By Dr. Hermann Mannheim. (Pp. 382. 18s. net.) London: George Allen and Unwin Ltd. 1940.

This book originated in the author's belief that there existed a noticeable gap in criminological and penological research which might profitably be filled by a study of the history of crime, its causes and treatment, in England during the last quarter of a century. He felt that only then had the time arrived for a detached assessment of the criminological implications of the war of 1914–18 and the period which immediately succeeded it, and for an examination of the practical working of the machinery created by the progressive legislation of the beginning of the century. His plan had to be modified in some ways, particularly by reshaping his survey of juvenile delinquency to avoid overlapping with the extensive research which had been started by the authorities. He first examines critically the structure and interpretation of English criminal statistics. He candidly recommends the non-technical reader to skip this lengthy section, but its place is obvious. It would be unsound to ask readers to accept conclusions based upon such an uncertain foundation as the English criminal statistics without a detailed study of their weak spots. He deals in separate chapters with the most significant aspects of the period between the wars, such as unemployment and strikes, business administration, alcoholism, and gambling, and with those aspects of crime which are associated with specific sections of the population, such as juvenile delinquency, prostitution, and recidivism. He has had the advantage of the support of the Leon Bequest Committee of the University of London, and has been able to use a large amount of official material. This is a real professional textbook, full of illuminating fact, in which experts in the study of every branch of crime will find much instruction.

THORACOPLASTY

La Thoracoplastie Élective: Primitive—d'Association—de Substitution. By J. Angirany, L. Michon, and A. de Micheaux. Preface by de F. Dumarest. (Pp. 128; 28 plates. $1.35.) Paris: Masson et Cie. 1940.

Most tuberculosis workers will agree with Dr. Dumarest that the enormous progress made in the treatment of pulmonary tuberculosis, particularly during the past ten years, is largely due to the development of a "symbiosis" between tuberculosis physician and surgeon. This monograph, written by a surgeon and two physicians, is based on four years' such collaborative work at one of the sanatoria at Hauteville, and reflects the modern tendency to confine the field of operation in thoracoplasty to the minimum required to obtain the maximum beneficial effect on the lesion; the extent and type of rib resection, including the surgical approach and number of stages, being planned beforehand to suit each case. Indeed, the authors have nothing good to say about total thoracoplasty—"everything must be done to avoid it," a complementary phrenicectomy being preferable where a total thoracoplasty seems indicated.

Though written almost in note form the book is very readable. Essentially an account of personal experience, it nevertheless contains references to other workers, particularly in the first chapter, on the evolution of the ideas on thoracoplasty; and there is a useful bibliography. The case reports are excellently illustrated. The indications are clearly set out. They are classified as general indications (good, borderline, poor) for thoracoplasty *d'emblée* or *primitive*; as those for complementary thoracoplasties (*d'association*), when the operation supplements a phrenicectomy, a contralateral pneumothorax, or a partially effective pneumothorax; and as indictions for thoracoplasty *de substitution*, when it is carried out because an intrapleural or extrapleural pneumothorax has proved ineffective. The authors stress the importance of normal tissue all round the cavity in obtaining a really good result, and the influence of this fact on the planning of the operation.

There is a good chapter on anaesthesia, in which the role of premedication is emphasized. The section on technique is detailed, but suffers from absence of illustrations. The final sections, on "results," are concerned mainly with complications (inadequately discussed) and sequelae, including effects on the skeleton, but no actual results are given except the figure of 2% as the immediate operative mortality. And there is nowhere in the book any indication of the number of patients on whom the authors have operated. The monograph will be found useful by tuberculosis physicians who wish to have more than a nodding acquaintance with details of surgical interventions.

HISTOLOGY

Bailey's Textbook of Histology. Edited by Philip E. Smith, Ph.D., Russell L. Carpenter, Ph.D., Charles M. Goss, M.D., Wilfred M. Copenhaver, Ph.D., and Aura E. Severinghaus, Ph.D. Tenth edition. (Pp. 764; 448 illustrations, many in colour. 33s. net.) London: Baillière, Tindall and Cox. 1940.

A Textbook of Histology. By Harvey Ernest Jordan, A.M., Ph.D. Eighth edition. (Pp. 690; illustrated. 35s. net.) New York and London: D. Appleton-Century Company, Inc.

Each of these new editions of two well-known American textbooks on histology has certain special characteristics which distinguish the one from the other, while at the same time they possess many points in common. Among the latter are: the width of scope and diversity of the subject-matter, which has been systematically dealt with and described in detail; the general excellence of the illustrations, many of which are colour plates; and an endeavour to record the results of a vast amount of recent research work on general and experimental human histology in book form, so that it is easily accessible to the ordinary reader. The two volumes differ in that the one is the combined work of five authors, whereas the other may be considered as the life's work of a single individual who has devoted his whole energy to the study of human histology. Each method has advantages over the other. The co-operative method, represented by *Bailey's Histology*, is perhaps best suited for research workers and authors as a book of reference; whereas the work of a single author, exemplified by Jordan's *Histology*, is more likely to bear the hall-mark of individuality and be preferred by a reader approaching the subject for the first time.

Although references to the clinical bearing of certain facts of histology might be considered as outside the scope of a work on microscopical anatomy, yet, as textbooks on human histology are mainly written for the use of students of medicine, such references are of great value and add to the interest of the description. A good example of this is found in the pioneer work on the structure and formation of bone, which was largely carried out by or at the instigation of British and French surgeons, who

combined their own clinical observations with experimental and histological research. These earlier works are so fundamental that no account of bone formation or of its repair can be considered as historically complete without some reference to them. Fuller references to foreign literature, more especially to the German, Spanish, and Italian work on the central nervous system, are desirable; the two books, however, may be regarded as containing all the more essential facts of human histology, and may confidently be recommended for the use of both junior and advanced students of that subject.

Notes on Books

In *Haemophilia and Egg-white Derivatives* Dr. W. A. TIMPERLEY makes a full statement of his claim that a substance which can be extracted from egg-white reduces the clotting-time and arrests haemorrhage in haemophilia. This compilation consists largely of case-histories, but the method of preparing the extract and other technical procedures are briefly described. The theoretical argument which led to the adoption of this method is far from clear, and the reader of the brochure will probably feel that the various effects claimed for egg-white derivatives—for there are several—must be classed as empirical, even supposing that they are accepted as constant and regularly reproducible. Copies, price 6s. 6d., can be obtained from Dr. Timperley, 4, Blackmoor Crescent, Norton, Sheffield, or through Messrs. Jowett and Sowry of Leeds.

The seventy-third annual volume of *Whitaker's Almanack*, for 1941, has now appeared in three forms—at 15s. and at 10s., and an abridged edition, with paper covers, at 5s. Like many other persons, publications, and institutions *Whitaker* has not escaped war damage. Publication was postponed because bombs blasted its printers while the book was being machined, and then the home from which it had been issued for nearly three-quarters of a century was destroyed in the second Fire of London. The events of the war are chronicled in this edition, and the new departments that have been set up occupy many pages.

The Pharmacology and Therapeutics of the Materia Medica, by Prof. W. J. DILLING, is the sixteenth edition of the textbook originally written by Dr. J. Mitchell Bruce and afterwards edited jointly by Bruce and Dilling. The general arrangement has been preserved, and the text has now been brought up to date once more so as to contain accounts of all the drugs currently accepted and widely used as therapeutic agents. Important drugs of recent introduction are described, also others that promise to be of value. This edition employs the official pharmacopoeial names for drugs hitherto referred to under trade names. The book is published by Cassell and Co. at 12s.

Preparations and Appliances

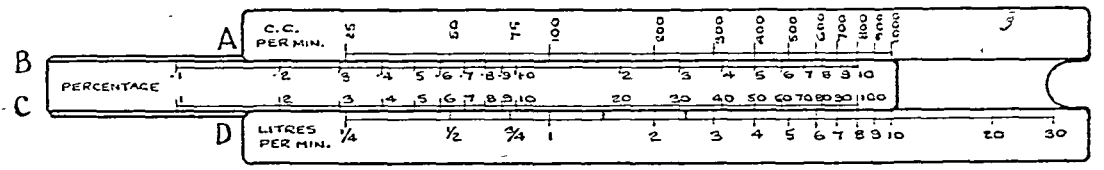
ANAESTHETIST'S SLIDE RULE

Dr. WILLIAM W. MUSHIN (Honorary Anaesthetist, Seamen's Hospital, Greenwich) writes:

The anaesthetist is more interested, from a physiological and record-keeping point of view, in the qualitative composition of the gas mixture his patient is breathing than in the actual volumes of each gas delivered per minute. The intermittent-flow machines, such as the McKesson and the Walton, are calibrated qualitatively, and the percentage of each gas can be read off directly. In contrast to this the continuous-flow type of machine, exemplified by the Connell, the Foregger, and the Boyle, which has been supplied by the Government throughout the country, is fitted with flowmeters which indicate the volume flow of each gas in unit time. The anaesthetist using these machines must himself calculate the percentage composition of the mixture from these flow rates, and this calculation has to be repeated whenever the flow of any of the gases is altered. When only two gases are being used and the figures are simple, the calculation is an easy mental one. However, with more than two gases and with fractional rates of flow a mechanical calculator has proved of great value, and has made the visualization of the qualitative changes in mixture easy.

A simple calibrator has been devised which makes easy this conversion of the quantitative reading of gas flow given by the flowmeters into a qualitative form. It also indicates what flow rates will be required to produce a mixture of desired composition. The scales are logarithmic, the figures representing the logarithm of the number indicated. The principle is therefore that of the engineer's log.-log. slide rule. The calculation desired is solved by the equation:

$$\frac{\text{Volume of gas A in litres per min. } (V_a)}{\text{Total volume of gases in litres per min. } (V_t)} \times 100 = \text{Percentage of gas A in mixture } (P_a)$$



or, in logarithmic form:

$$\log 100 - \log V_t \div \log V_a = \log P_a$$

The equation has thus been reduced to a simple one of addition and subtraction, and the answer can be read off on the slide rule with accuracy.

Use of the Instrument.—The anaesthetist's slide rule consists of two fixed scales, A and D, for the gas-flow rates, and two sliding scales, B and C, for the percentage figures (see illustration). For average use scales C and D only are required. Scales A and B are employed when very slow rates of flow—under one litre per minute—are being used, such as with basal oxygen and cyclopropane. The slide is adjusted so that the 100 mark on scale C (marked in red on the instrument) is exactly opposite the figure for the total volume of gases on scale D. The percentage of any gas in the mixture is read off on scale C opposite the volume-flow rate for that gas in scale D. The calculation $\log 100 - \log V_t - \log V_a$ has been performed in that order, and the answer is found in scale C.

Examples.—(1) 6 litres of N_2O, 1½ litres O_2, and ½ litre of CO_2 are indicated on the machine. What is the percentage composition of the mixture? Total volume of gases per minute = 8 litres. Move the slide till the 100 mark in red is opposite 8 litres (as in illustration). The figure 6 is opposite 75, which is the percentage of N_2O; 1½ is opposite 18¾, which is the oxygen percentage; and similarly the CO_2 is just over 6%. (2) 6 litres of N_2O are flowing. What flow rate of oxygen is required to give 25%? (Simple figures have been chosen so that the illustration can be used to follow this example.) The N_2O percentage is therefore 75. The figure 75 on the percentage scale C is brought opposite 6 litres on scale D. The oxygen flow required is read under the figure 25, and is 2 litres per minute.

This anaesthetist's slide rule has been beautifully made for me by the British Oxygen Co., Ltd., Wembley, Middlesex, who propose to issue it as part of the equipment of the Boyle machine. My thanks are due to Mr. G. F. Arcus, their technical adviser, for his help and valuable suggestions.

ANTISEPTIC SNUFFS

It is a truism that the control of air-borne infections has lagged far behind other forms of progress in hygiene. Water, food, and animals as sources of infection we know how to tackle, but aerial spread—which is responsible for a greater number of diseases than any other—continues almost unabated. More spacious buildings and better ventilation have doubtless improved matters, as have the detection and isolation of carriers as well as cases of certain infectious diseases, but widespread epidemics of influenza still testify almost every year to our powerlessness in the face of atmospheric contamination. The exigencies of war have called forth an active interest in this subject, and proposals are afoot for disinfecting air by chemical or physical means and for laying infected dust.

Where infections of the air passages are concerned an alternative is some measure of individual protection, but face masks, besides being unsightly and inconvenient, are known rather to protect other people against infection from the wearer than vice versa. That an antiseptic could be used for this purpose will have presented itself as a serious proposition to few people, in spite of the widespread use of lozenges and tablets, gargles and sprays, with the ostensible object of killing micro-organisms in the throat and nose. The efficacy of such measures is singularly ill supported, and the continuity of action necessary for prevention as distinct from cure can clearly not be secured by most of them. Nevertheless, Prof. M. E. Delafield, Dr. Edith Straker, and Prof. W. W. C. Topley, whose paper appears at page 145 of this issue of the *Journal*, have entered this apparently unpromising field and made observations which will arouse widespread interest. They speedily concluded that persistent antisepsis in the throat is an impossibility, and that attention must be directed to the nose. Here an antiseptic in finely particulate form can be widely distributed by taking it as a snuff: indeed, its distribution will be similar to that of inhaled bacteria. The clearing of secretion from the nose is much more leisurely than the corresponding process in the throat, and slow solution of an antiseptic introduced in solid form should add to the persistence of its action. A technique had to be devised for estimating the effects of this proceeding, and the quantitative method of cultivating swabs which was eventually adopted may well serve as a model for future observations in this field, where adjectives such as "profuse" and "scanty" applied to the growths obtained in culture are usually the nearest approach to any estimate of bacterial numbers. Where abnormal secretion is obtainable in bulk it would of course be possible to advance on this method by making a suspension from a measured volume, thus eliminating the main variable—which is the quantity of secretion removed by the swab. The effect of antiseptic snuffs was judged by the diminution in numbers of bacteria previously present, and noses whose secretion contained numerous staphylococci furnished the best subjects for experiment. Snuffs containing proflavine, penicillin, and sulphathiazole all caused a decided diminution in the numbers of staphylococci; proflavine was less regular in its effect, and staining is a serious aesthetic objection to its use. In several cases a diphtheroid bacillus disappeared rapidly and completely during treatment with sulphathiazole snuff.

These observations are only of a preliminary nature, and it will be interesting to see where they lead. It is fortunate that two antiseptics have at once been identified which not only secure an effect but are calculated to do no harm to the nasal mucosa. The ciliated epithelium of the nose is a delicate and valuable structure, constantly at work in the disposal of inhaled bacteria; the cinematographic demonstration of its activity, and of the impairment or cessation of this activity when even weak antiseptics are applied, given some years ago to the Section of Oto-rhino-laryngology of the Royal Society of Medicine must have convinced everyone who saw it that to tamper with this mechanism is something not lightly to be undertaken. A recent attempt at prophylaxis by antiseptic treatment of the nose must certainly have caused severe damage: this is the use of astringents (tannic acid, picric acid, alum, zinc sulphate) for tanning the nasal mucosa and so rendering it impermeable to the virus of poliomyelitis, a practice advocated in the U.S.A.[1-5] The choice of really innocuous antiseptics is small: another possible one is the bacterial extract studied by Dubos,[6] which has a remarkable action *in vivo* as well as *in vitro* on Gram-positive cocci, especially pneumococci. This substance and penicillin, which is of similar origin, have no action at all on many Gram-negative bacteria; according to the purpose for which nasal antiseptics are employed, these peculiarities in selective action will have to be borne in mind.

The main question at the moment is whether this form of treatment is going to be adopted as a means of prophylaxis—the original intention of its authors—or whether it is to be applied to the treatment of established nasal infections. The laryngologist will not be slow to adopt so novel and simple a treatment sponsored, however guardedly, by such authorities. Let us hope that he will not be disappointed, and let us hope also that careful studies may be made in order to decide what the treatment is capable of doing. The nasal diphtheria carrier—if he is old enough to learn how to take snuff—is a well-defined subject for attack; the meningococcus carrier and the sufferer from nasal catarrh due to a known and susceptible micro-organism are others. But let it not be lightly assumed that the inflamed mucosa will respond in the same way as the normal; that a profuse and purulent or inspissated secretion is as

favourable a menstruum for this effect as normal mucus, or that the various sinuses are as accessible to it as the main cavity of the nose. All these things remain to be found out if this form of treatment is to receive further serious study. It has further to be borne in mind that prophylaxis and treatment are very different things where an antiseptic is concerned: of the two, the former is the more likely to succeed. If either does so, it will be an unexpected achievement for a type of proceeding which it has long been customary to regard with scepticism and even contempt.

DOCTORS AND THE PURCHASE TAX

"Muddle" is not too harsh a word to describe the administration of the purchase tax so far as drugs and medicinal preparations are concerned. The situation changes almost from week to week with successive amendments issued by the Commissioners of Customs and Excise. On calling at the Customs House our representative was handed the Notice (No. 78) setting out what goods are chargeable with tax, but it was accompanied by two addenda cancelling or amending certain of the lists, and he was informed that even then the revision was not up to date. It seems improbable that any printed memorandum can ever be up to date. The continual amendments create an embarrassing position for the drug manufacturing concerns, which are having to refund tax already charged on articles newly exempted or to charge tax on articles which have been brought retrospectively under the Act. The trouble seems to arise from the fact that the tax is administered by civil servants with no real knowledge of drugs. No pharmacist is responsible, and there is no pharmaceutical control over the incidence of the tax or the choice of preparations for chargeability or exemption. Certain articles are not taxable if supplied by wholesale drug houses to chemists for industrial purposes, but are taxable if supplied either to chemists or doctors for medicinal use. A large number of simple drugs and single chemical compounds have industrial as well as medicinal uses, although the medical man may well think with regard to a number of them that their main or their only employment is in therapeutics. But they are only tax-free when not put up for medicinal, veterinary, or toilet use. Obviously a doctor would buy these preparations only for medicinal purposes, and therefore his purchases cannot be exempted. In the case of the chemist, the wholesaler, who pays the tax and recovers it at the point of delivery to the retailer, can only supply him free of tax if he is assured that the goods are not for medicinal use.

What are officially described as "essential drugs of an exceptionally costly character" are exempted altogether from tax. It is a clumsy definition, and the first list issued is obviously incomplete. Notice of revision has been given, but at the moment of writing the revision has not appeared. Examples of the drugs included in the free list are cocaine, insulin, oxygen, sera, vaccines, sulphanilamide, and hormones, including liver and liver extracts. But "hormones," according to the ruling given presumably on the advice of the Government chemist, do not include thyroid preparations. The drugs which are included in this class are free from tax no matter to whom supplied, whether hospital, doctor, or retail chemist. Another point worth noting is that diagnostic agents are free from tax. Then there is a class of drugs which is subject to a tax of 16⅔% (the full tax is 33⅓%). These include all the drugs and compounds which are the subject of monographs or submonographs in the *British Pharmacopoeia* and the *British Pharmaceutical Codex*, but there is a list of over 300 exceptions which, as already stated, are exempt from tax if the preparations are not put up for medicinal, veterinary, or toilet use. These include, for example, the salts of bismuth, iron, lead, magnesium, and sodium, also camphor, ether, and liquid paraffin, and such a preparation as benzyl benzoate, now much sought after for dealing with lice. The latest additions to this list include catechu, methyl chloride, and sulphurous acid, among other articles. A third group comprises the compounded medicinal preparations for the treatment or prevention of human or animal ailments; these again are chargeable at 16⅔%. Thus capsules, confections, emulsions, infusions, liniments, lozenges, ointments, pills, tinctures, tablets, and syrups are subject to this lower rate of tax, whether supplied to a retail chemist for re-sale or to a doctor for use in his practice.

There remain a number of articles not specified in the lists on which the Customs authorities have given specific rulings as to whether they are or are not chargeable, and, if chargeable, at what rate. Into this category, for example, come rubber hot-water bottles (which are now charged at 33⅓%). As for medicated foods and drinks, the line has been taken that preparations employed primarily for medical purposes are taxable (again at 16⅔%), but that plain unmedicated foods, like meat extracts and essences, infants' milk foods, and also foods prepared for diabetics where the preparation is intended merely to eliminate substances such as sugar and starch, are exempt. Cod-liver oil is given as chargeable in the Notice, but is now tax-free, as are cod-liver oil capsules. But cod-liver oil emulsion with hypophosphites is chargeable: only the simple emulsion is allowed to get through the index. Vitaminized glucose and similar vitaminized preparations are also now exempt, provided they do not contain any other medicaments. Chloroform is tax-free only when supplied for use as an anaesthetic or reagent.

Many anomalies remain. It appears, for example, that a chemist may buy certain ingredients, such as those of pulv. bismuthi co., free of tax, but if he buys pulv. bismuthi co. he pays tax. On the other hand, seeing that cinchona bark, cassia pods, capsicum, and similar natural raw materials, not prepared or put up as drugs or medicines, are exempt from tax, it would seem that if someone bought an entire senna shrub it would not be chargeable, but if he bought the pods nicely put up it would be. The position with regard to natural drugs is not at all clear. All surgical appliances made from fabric materials, if prepared to a medical prescription, are tax-free, but it is essential that the name of the patient as well as of the doctor should be given. The tax does not apply to surgical boots or corsets made to the prescription of a medical

practitioner, again with reference to the needs of a particular patient. All surgical dressings are exempt. Bed-pans, urinals, etc., are subject to tax at 33⅓%; and so are eye-baths, whether sold to the chemist or the doctor. Douches, pestles and mortars, inhalers, syringes, and vaporizers are not chargeable.

The really difficult point in the administration turns upon the drugs which when supplied for industrial use are exempt from the tax and when for medicinal use are subject to tax, though at half rate. The question may be asked whether the chemists are not gaining an unfair advantage, but it should be remembered that all these matters are subject to control by the Price of Goods Act, and the Central Price Regulation Committee has already issued a guide to maximum prices. The chemist is careful not to charge excessively, and he has a high reputation to sustain. He certainly has some advantage over the dispensing doctor when both are subject to the tax, because the chemist receives a higher discount from the drug houses, and, the tax being levied on the wholesale price, he pays tax on a smaller amount. Admittedly, the chemist and the dispensing doctor are not in entirely comparable positions, and commercial considerations which obtain in the one case do not obtain in the other. Nevertheless, the situation needs careful watching lest, almost by inadvertence, a different rate of tax for doctor and for chemist is perpetuated.

CEREBROSPINAL MENINGITIS

We are now entering on the season when an increase in the incidence of cerebrospinal meningitis is to be expected; and a rise is in fact occurring, though so far it is relatively small. It may therefore be of some interest to note the lessons that we learned during the major outbreak that occurred in the winter and spring of last year. The essential fact that emerged from that experience was the vital importance of early diagnosis. It is clear that the sulphonamide compounds, and particularly, perhaps, sulphapyridine, have placed in our hands a remedy which, if it is used in time, will reduce the mortality from this disease to a small fraction of its former dimensions. It is easier to secure early diagnosis among troops under discipline than among the civil population, if only because, in civilian life, the doctor may be called in too late; and the experience of last spring made it clear that many lives were being lost that would have been saved if treatment had been instituted more promptly. The practitioner can play a vital part in reducing the case mortality from this disease by exercising a constant watchfulness for the earliest symptoms, by having the cerebrospinal fluid tested promptly in any doubtful case, and by giving precautionary and adequate doses of sulphapyridine, or of sulphanilamide, while a bacteriological diagnosis is being established. Care should, of course, be taken to discontinue the drug if the laboratory findings are negative, and to inform any hospital to which a case is admitted of the exact doses that have already been given. The other lesson that we learned last year, though many had taught it before, was the uselessness of swabbing contacts. It has become clear that carrier rates of 50% or more may be found in large sample swabbings of aggregations of men among whom few or no cases are occurring. In these circumstances the isolation of a few unfortunate carriers will produce no significant decrease in the risk of infection to which others are subjected; while the inconvenience and mental distress resulting from such isolation are by no means negligible. Beyond sending to hospital or isolating the actual case our efforts may be confined to the avoidance of overcrowding, and to any other procedure that is likely to reduce the risk of the passage of bacteria from one person's nasopharynx to that of another. In the light of our present knowledge the swabbing of contacts should be discontinued.

ENTER THE INDUSTRIAL PSYCHOLOGIST

Some while ago Mr. Herbert Morrison startled the public with the slogan "Go to it"; whereupon some people had a vision of munition workers and others in industry feverishly quickening their pace until by the extra labour of their hands twenty thousand shell fuse cases were turned out where only ten thousand had been turned out before. The problem of increased production is not solved as easily as that, and it is very likely that such an acceleration would result in human fatigue and waste of material quite out of proportion to any gain. The psychologist in industry in normal times was a kind of occasional consultant, whose help was sought only by some very up-to-date firms, but under war stress he may well become a general practitioner whose services are wanted everywhere and all the time. In the factories of this country an unprecedented number of people are at present being put to new jobs, and their rapid training is an important part of the war effort. The National Institute of Industrial Psychology has issued a threepenny pamphlet on the training of industrial workers, and into a dozen pages it has compressed a great deal of wise advice. That it is possible greatly to accelerate training in industrial processes is well known to all who have given any study to this subject. It is said that operatives in one process of coil winding can now be trained in five days to a level previously attained only in five weeks, and that in spite of the intensified training the scrap rate has actually fallen. Months or even years of experience have been regarded as necessary for the newcomer in industry. But of what sort of experience? Often the experience of watching and copying a so-called experienced worker who may be quite unsuited to give any teaching and may not be employing the best procedure himself. Or it may be that the newcomer gains experience by working out his methods for himself after being told what to do, thereby learning from his mistakes—a difficult and painful process—or settling down to a second-best way of doing things, which means uneconomical expenditure of effort and too often unsatisfactory results, wasted time, spoiled material, and general discouragement. The Institute insists that the first thing to be done is to choose a trainer for new entrants into industry—a man who not only knows his job but has the ability and temperament suited for the teaching of young workers. The training should take place away from the noise and distraction of workshops, the job should be studied and a systematic course of instruction planned. In skilled trades like engineering the learner must know a great deal about the job itself, not merely concentrate on his little repetitive process. Then there is movement study on which in the past a great deal of work has been done, primarily with a view to the saving of time and energy. In very many factories no instruction at all is given concerning correct movement. The learner works out his own movements and uses many which are unnecessary. A case is mentioned in which on one particular process it was found possible to reduce the number of working elements from 265 to 148. The task of the psychologist depends on what is known as job

analysis. He takes advantage of the various improvements in movement and in the disposition of material which suggest themselves. Often it is found that only one hand is being used to carry out a job in which both hands might easily participate. Materials and equipment are not kept in prescribed positions in which they could be picked up without conscious thought (here the industrialist might learn a lesson from the disposition of the operating theatre or the first-aid post). The booklet mentioned advises as to the choice of trainer to instruct in standard procedure. It is necessary, of course, for any trainer to bear in mind that a great deal of industrial work is monotonous, and that the young people in his charge may have recently left school, where they have been accustomed to short lessons and a varied session. Therefore he will arrange for changes in activity if possible, and he will also accommodate his requirements to individual differences in ability and in aptitude for learning, which may justify certain variations from the standard procedure. The methods of the drill sergeant are not called for in industry.

PANCREATIC ENZYMES IN THE BLOOD

The determination of urinary diastase is a time-honoured procedure; the estimation of the same enzyme in the blood has been less popular, and serum lipase has suffered from a similar neglect. Interest attaches, therefore, to 616 determinations of serum lipase on 371 patients by Johnson and Bockus.[1] They consider values exceeding 1 c.cm. of N/20 NaOH as pathological, and their highest reading was 5.5 c.cm. Broadly speaking, high results appeared to indicate pancreatic disease. Thus nine out of eleven cases of acute pancreatitis and five out of eight cases of carcinoma of the pancreas gave readings above 1 c.cm. at some stage of the disease. The few positive results in other diseases could be plausibly explained on the basis of disturbance of pancreatic function—for example, nine out of twenty-nine cases of gall-stones with obstructive jaundice. But high readings were obtained in four patients with intestinal obstruction. Clinically this is unfortunate, as the diagnosis of acute pancreatitis from intestinal obstruction is one in which help would naturally be expected from estimation of serum lipase. Liver diseases, diabetes mellitus, hyperthyroidism, malignant disease, peptic ulcer, and a variety of other conditions usually gave normal results. It is pointed out that the test is unsuited to the investigation of urgent conditions, as it takes twenty-four hours to perform. The serum diastase has been studied recently by Somogyi,[2] who has evolved two rapid and improved methods of determining this enzyme; the "saccharimetric" method appears to be the most effective: it is based upon copper reduction and is expressed as the equivalent of a blood-sugar value, figures between 80 and 150 being considered normal. It is generally agreed that much-increased values are the rule in acute pancreatitis, and according to Probstein, Wheeler, and Gray[3] moderate increases may be seen in perforated peptic ulcer involving the pancreatic region. Less work has been done on chronic conditions, but Somogyi[4] expresses the opinion that low values indicate hepatic damage. No definite proof of this statement is, however, adduced, and the slight reduction of serum diastase which he reports in diabetes mellitus would appear to be better explained on the basis of impaired pancreatic function. Finally, Comfort and Osterberg[5] have compared the value of the two estimations in a large series of cases of pancreatic disease. They found that both enzymes form a good index of active or acute pancreatitis, the lipase being raised in about 98% and the diastase in about 88% of such cases. The tests should be done within ten days of the onset of the symptoms if possible. In pancreatic carcinoma, on the other hand, the lipase was elevated in 40% and the diastase in only 8% of the cases. Raised values in other conditions—for example, gall-stones, peptic ulcer, carcinoma of stomach—could always be correlated with pancreatic involvement except for a few of the cases of hepatic disease which showed slight elevations of serum lipase. It should be noted that these authors accept a wider range of normal values than those first mentioned, figures up to 1.5 c.cm. and 320 units (Somogyi) being taken as normal for lipase and diastase respectively.

PROBLEM OF NEONATAL MORTALITY

It is well known that the striking decline in the infant mortality rate during the past fifty years has not been equal at all ages. Over 100 years ago T. R. Edmonds in this country was one of the first to point out that it was the high death rate among infants in the first few weeks of life which accounted mainly for the high mortality figure for children under 1 year. It is generally agreed that improvement in environment and in protection against infection, more especially against intestinal infection, have been the chief factors responsible for the general downward trend of infantile mortality, but, even so, neonatal mortality remains unaltered. H. Seibert in a recent paper[1] pays particular attention to this problem of neonatal death, and discusses many factors which indicate a biological basis for the failure of the babies to survive. Age of the mother, parity, and multiple births are influencing factors and uncontrollable. The complications of labour may be averted in some instances and not in others. "If the pregnant woman," he writes, "could have the correct nourishment, good ante-natal care with rest, and if she were also free of any puerperal complications, then the newborn would issue into the world with a better chance of successfully surviving the dangerous neonatal period. But even with the best of care under the guidance of an expert obstetrician there are bound to occur some circumstances that cannot be foreseen. The process of being born is a dangerous one, and birth traumas account for a large part of the causes of death of the newborn." It is possible that in the future some of the risk of birth trauma may be reduced by the use of vitamin K to control intracranial haemorrhage, as was suggested in these columns earlier this year,[2] but Seibert notes from his study of the history of the subject that as one symptom appears to be coming under control others gain ascendancy. He thinks that there is still much to be learnt about neonatal mortality, and he is inclined to look for this, although not necessarily for a reduction in mortality, in the biological factor of constitution. One fact which favours this view is the excess mortality in male as compared with female infants. When infantile mortality rates are high both sexes are carried off more or less indiscriminately, but when the general infantile mortality rate is low it is found that more male infants die than female. This, it is claimed by some workers, is due to a purely constitutional weakness in the male sex. It is also suggested that from biological causes the fertilized ovum is "bad" from the beginning, and that no amount of protection or pre-natal care will alter the fact and prevent stillbirth or death in the early weeks

[1] *Bull. Hist. Med.*, 1940, 8, 545.
[2] *British Medical Journal*, 1940, 1, 839, 856.

of life. Animal studies indicate that a considerable amount of pre-natal death is normal in mammals, and even careful pathological examination fails to find any abnormal conditions in the dead foetus or infant. The term "congenital debility" only serves as a cloak for ignorance of such deaths. Despite the obvious pessimism of this biological point of view, there seems reason to hope that the problem of infantile mortality in the neonatal period may be tackled more energetically along certain lines. Better control of diet during pregnancy, rest for the mother for longer periods before delivery, longer intervals between pregnancies, and better teamwork in the management of the premature baby, are all ways in which some improvement might be achieved. Seibert's historical study indicates clearly what has been done in general for the young child and the successful results obtained. He also shows how little appears to have been done towards a solution of the problems of the newborn.

TREATMENT OF GAS GANGRENE

Little was known at the outbreak of war about the capacity of sulphonamide compounds for preventing or controlling gas gangrene, although such evidence as already existed was encouraging. It was clearly necessary to explore this neglected problem at once, and several experimental studies were set on foot in the hope of providing data which would serve as a guide to clinical policy. Anyone who has carefully studied the results already published by D. Stephenson and H. E. Ross[1] and by D. W. Henderson and P. A. Gorer[2] must have understood that this study has proved unexpectedly complex; factors affecting the therapeutic results in mice are not only the choice of drug and the species of *Clostridium*, but the toxigenicity of the strain used, the route of inoculation, and the menstruum. That subsidiary factors such as these last three should materially affect the outcome of an experiment is evidence in itself that the power of control exerted by sulphonamide compounds over anaerobic infections is far from absolute; indeed, it is probably of a lower order than its capacity for controlling infections by haemolytic streptococci. The subject has also been studied by E. Singer,[3] working at the Baker Medical Research Institute, Melbourne, and his findings agree in the main with those of other workers. They confirm the complete insusceptibility of *Cl. oedematiens* infection to chemotherapy, and the greatly enhanced therapeutic effect obtained in *Cl. welchii* and *Cl. septique* infections by combining antitoxin and sulphanilamide or sulphapyridine treatment. These experiments on this point indicate that giving a small dose of antitoxin greatly reduces the amount of drug required to secure survival; this combined efficacy of amounts of each therapeutic agent, either of which alone would be quite inadequate, further illustrates the synergic action described by Henderson and Gorer. Singer also describes experiments which suggest that desoxycorticosterone has some protective action against *Cl. welchii* toxin; since the hormone was given the day before the toxin it does not follow that this proceeding has anything more than prophylactic value, but the observation is neither an isolated one nor altogether empirical, and evidently merits further pursuit. If the results of these now numerous mouse experiments are neither as encouraging as might have been hoped nor as yet conclusive on certain points—such, for instance, as the relative merits of sulphanilamide and sulphapyridine—they do at least form an adequate basis for clinical experiment, and only by this means is useful knowledge now likely to be advanced much further. Cases of gas gangrene have presumably not been unknown among recent air-raid casualties, but we have yet to hear how they have been treated and with what results. Every such case is an opportunity for observations which may be of great value, and no effort should be neglected to secure its adequate study, which must of course include bacteriological as well as carefully recorded clinical data.

EMPIRE RHEUMATISM COUNCIL

The fourth annual report of the Empire Rheumatism Council is occupied largely with an account of services given to the defence Forces. Its Naval Research Foundation has continued to work with its headquarters at the emergency station of the Royal Naval Medical School; an invitation from the Royal Air Force Medical Service to assist in its plans for the treatment of rheumatic disease has been promptly accepted; and as regards the Army, the council has sought the establishment of special hospitals for the treatment of this disease. It is considered that a high incidence of rheumatic disease among soldiers is likely to arise, because, apart from other conditions of service, the intensive development of mechanized warfare makes them subject to frequent small bruising and tearing injuries and to the effects of working in cramped positions and frequent alternations of heat and cold—the environment, in fact, which is productive of rheumatic disease in industrial life. It has been deemed wise to concentrate the expert knowledge of medical men having a wide experience of the diagnosis and treatment of rheumatism in specialized hospitals; a plan to this effect has been submitted, and the council has offered its help in the fullest measure. An administrative problem, however, arises—namely, that the physical treatments which are necessary in dealing with rheumatic disease are also frequently called for in the rehabilitation of joints, muscles, and nerves injured by wounds. It is considered inadvisable to duplicate the medical and auxiliary personnel or the technical equipment, but it will not be forgotten that a very large proportion of the cases to be treated by these measures are rheumatic, and that rheumatism is primarily the care of the physician, although in many cases valuable help can be given by the orthopaedic surgeon. One of the two Sir Alexander Maclean Laboratories was suspended last year; the other continued until October, 1940, when its work was interrupted as the result of enemy action. Sir Alexander Maclean has intimated his willingness that funds from his generous gift should be diverted, as and when necessary, from the original objectives to any work for the defence services which the council undertakes. The report records the reopening in February, 1940, of the British Red Cross Clinic for Rheumatism, in Peto Place, as a most welcome restoration of treatment facilities in London. The West London Hospital rheumatism department has also been reopened.

We regret to record the death of two distinguished former officers of the Royal Army Medical Corps: Colonel Sir William Horrocks, aged 81, who was a member of the Mediterranean Fever Commission sent out by the Royal Society in 1904–5, and afterwards Director of Hygiene, War Office; and Major-General Sir George Stanistreet, aged 74, who was Deputy Director-General, A.M.S., 1918–22. The death is also announced of Dr. W. Cecil Bosanquet, consulting physician to Charing Cross Hospital and the Hospital for Consumption, Brompton.

ARMY MEDICAL OFFICERS AND MAN-MASTERSHIP

Well over a hundred R.A.M.C. officers were present when the Corps Commander, Lieut.-General A. F. A. N. THORNE, C.B., C.M.G., D.S.O., delivered his introductory address at the commencement of Corps Study Week (Medical). He began by saying he was glad of this opportunity of meeting so many of the medical officers of his Corps and that, during the short time he had at his disposal to talk to them, he wished to emphasize the important part that the medical officer could play in the life of a unit. The first and most important contribution that a medical officer could make to efficiency lay in the effort he could put forth to improve the standard of man-mastership. The principle of economy of force was of vital importance in war, and whenever a soldier, whether mentally or physically sick, was returned to duty, the medical officer had repaired some of the efficiency which would otherwise have been lost to his unit. There were literally hundreds of men who never came into the category of casualties in the true sense of the word. If the man-mastership of the unit was not of a high order these men will be the cause of a huge and avoidable loss of efficiency through their poor performance and feeble endurance. It was this avoidable loss which could and must be prevented; it could best be done by full co-operation between the medical officer and the regimental commander. The malingerer invariably appeared when hard times were experienced, but the loss of man-power through this cause must not be allowed to lessen the efficiency of the unit, which it undoubtedly would unless the medical officer took a strong line. Under a weak medical officer sick parades, instead of consisting of a few genuine cases, might come to resemble a battalion on parade.

From experience gained during five and a half years as a battalion commander, General Thorne said that the most striking lesson he had learned was the enormous amount of reliance a commanding officer must place in his padre and in his medical officer in order to raise the standard of man-mastership to a high level. Their knowledge of psychology and physiology should fit them to estimate character and to understand human nature and so to gauge the strength and endurance of individual men. While it was a mistake to impose too light a task, too heavy a task might lead to demoralization; and it was here that the advice of the medical officer should be of inestimable value.

Assessment of the Individual Soldier

The work of building up man-mastership must be done before the unit was engaged in active operations, otherwise the medical officer would be too busy dealing with actual casualties to attempt to rectify losses resulting from bad man-mastership. It was the duty of the medical officer to study and understand each individual officer, warrant officer, and senior N.C.O. in his unit; to assess character and make-up, and to note the good and bad points. He should pass on his views to his commanding officer, so that each individual might be employed to the best advantage. In this way a potential leader was not likely to be lost sight of and side-tracked by extra-regimental employment. General Thorne stressed the importance of the medical officer accompanying the regimental officers when the men attend bathing parades. It was, in his opinion, an excellent opportunity to see the men stripped and to note their physical defects, so that corrective exercises could be ordered.

All officers, warrant officers, and senior N.C.O.s must be educated in man-mastership and hygiene. The more an officer understood the complexity of the human body the better he was able to understand the involved system of control and maintenance of an army. Several books and pamphlets had been published on this important aspect of regimental life, as the result of knowledge acquired during the last war. Of these, "The Load Carried by the Soldier," by Major Lothian (Army School of Hygiene), "The Report of the Southborough Shell Shock Committee," and "The Psychology of the Soldier," by Bartlett, were good examples. If studied, they would form a solid background of knowledge and understanding which would be of great value when instructing officers and other ranks. In concluding, the Corps Commander said that, in his view, man-mastership was an art, but that medical officers, by using their technical knowledge, could make it almost a science. This should be the aim of every medical officer.

The D.D.M.S. of the Corps, Brigadier L. T. POOLE, D.S.O., *M.C.*, K.H.P., in thanking the Corps Commander for his address, pointed out that unless medical officers fully realized the importance of the points he had made they could not expect to achieve that measure of success in the preservation of man-power which was of such vital importance. Preservation of man-power by means of good man-mastership was, and always must remain, the prime consideration of every medical officer in the field. He ended by emphasizing the value of the address in that it represented the views of an experienced regimental commander.

Planning a Medical Study Week

Study Week was planned in order to give the officers of the Corps a survey, by various leading authorities, of the knowledge which had been acquired during the past sixteen months of war. Many of the officers had perhaps had little opportunity in recent months to do much clinical work or to treat many casualties due to enemy action, and a week of intensive study was arranged to keep them abreast of the recent advances in the more technical side of their duties. Two lectures, each of which was followed by a short discussion, were delivered every afternoon. Colonel J. Weddell dealt with "General Principles of War Wounds"; Colonel Ogilvie, "Abdominal Injuries"; Mr. Julian Taylor, "Head Injuries"; Mr. N. R. Barrett, "Chest Injuries"; Colonel C. Max Page, "Fracture Treatment in War"; Dr. M. D. Nosworthy, "Anaesthesia in the Field"; Dr. C. Newman, "Dyspepsia in the Army"; Colonel J. R. Rees, "Neuroses in War"; Colonel L. Colebrook, "Chemotherapy of War Wounds"; Colonel A. W. Stott, "Meningococcal Infections"; and Colonel John T. Ingram, "Common Skin Diseases and V.D." It was evident from the large attendances, not only of R.A.M.C. officers but also E.M.S. doctors, and the warm way in which the lecturers were received, that the course had been greatly appreciated.

DRESS REHEARSAL AT FIRST-AID POST

One of the first-aid posts in London which has not received a sufficient number of casualties to satisfy its large and zealous staff has, under the direction of its medical officer, instituted a system of faked casualties, which are attended with the same care and routine as if they were from an actual incident. Nothing is more depressing to the first-aid worker than to tend supposed injuries which are invisible and left wholly to the imagination. Therefore an elaborate "make-up" has been introduced under the direction of a quartermaster who is skilled in this art, and the work is carried out as carefully as anything done behind the scenes at a theatre, and is as realistic in its results. Cellophane, vaseline, and various coloured dyes are used to give a very close resemblance to the appearance of a raw wound, and in the case of one of the frequent "victims"—an orderly with histrionic gifts—the resemblance is assisted by his disordered movements and mutterings.

Instruction by Film

A cinematograph film in direct colour by the kodachrome process has been taken of the method of "making-up" these "casualties," and is available for exhibition at other first-aid posts which may care to adopt this scheme of rehearsal. A second film has been made of the "casualties" being attended by the staff, but this has not yet been released. One subject in the first film is a third-degree burn in the back, apparently extending right down to the processes of the lumbar vertebrae. Another shows the right eye apparently forced out of its socket and lying on the cheek (the secret here is that the "victim's" eye has been covered over with some paste, and the detached eye is an artificial one). As described it sounds like amateur play-acting, but watching it, and noting especially the seriousness with which the nurses and orderlies get to

work on a case, one forgets, as they do, that it is make-believe. Any feeling of unreality tends to disappear when, as often happens, the noise of London's evening barrage accompanies the demonstration, and one knows that at any moment the rehearsal may be stopped because the real thing has begun.

Volunteer Casualties

Visitors to the post may be asked to act as "casualties." One of them indicated vaguely an injury to his wrist, whereupon he was taken by the orderlies to a couch in the treatment room, where he was examined by a competent nurse and her assistants, who dressed and bandaged the "wound." Then he was labelled with the casualty card giving his name and address and description of injury, assisted to the rest room, where he was given a cup of tea, and finally sent off to hospital in dummy, as it were. One member of the staff, again, simulated a crush wound of the foot. The torn and bleeding muscles and exposed bone were admirably made up, and still more admirable was the first aid administered under the oversight, but without the interference, of the medical officer. Another demonstration was of a rescue from a supposedly bombed building of a man with a fractured femur. A small cupboard difficult of access for any team of rescuers was made to represent the bombed interior, and the rescue squad gave a fine exhibition of resource and dexterity. The bringing out of the "casualty," the application of the Thomas splint to the patient lying on the stretcher, and the dispatch of the ambulance took place in record time. Incidentally, this was carried out with everybody wearing an anti-gas respirator.

Value of Faked Casualties

Faked casualties form a really useful part of the training. They are only a part, because drill of various kinds and lectures and cinematograph films also come into the daily routine. The purpose behind it is not only to instruct nurses, orderlies, stretcher-bearers, and A.R.P. workers in the technique of first aid, but to keep them in a state of alertness and adequacy alike for the major or minor emergency.

Reports of Societies

LOWER UTERINE SEGMENT

A meeting of the Section of Obstetrics of the Royal Academy of Medicine in Ireland was held on December 20, with the president, Dr. R. M. CORBET, in the chair.

Prof. O'DONEL BROWNE read a paper on the lower uterine segment and uterine descent. He reviewed the facts known about uterine support and the relative values of the utero-sacral and transverse cervical ligaments on the one hand, and the perineal muscles and fascial floor on the other. He regarded the former as the main support of the womb. During pregnancy, he said, the transverse cervical ligaments were spread fanwise upwards as a lateral brace between the broad ligaments, stabilizing the uterus. In a somewhat similar manner the utero-sacral ligaments decussated and spread out over the posterior surface of the lower two-thirds, strengthening the new lower uterine segment and preventing the heavy fundus from falling forward. Prolonged and strong uterine contractions, or forcible delivery through an undilated cervix, might easily rupture these taut and widely separated ligamentous bands. Forcible downward traction would tear the lower fibres, detaching the vaginal vault from the under surface of the pelvic ligamentous support. The resulting pull of the unsupported cervix on the still fixed higher part produced supravaginal hypertrophy. If both upper and lower ligaments were torn the uterus would descend. High rectocele was a true hernia in Douglas's pouch, between the adjacent borders of the utero-sacral ligaments. This rather rare condition was cured by approximating the two ligaments, either from above or per vaginam. The extensive colpoperineorrhaphy which cured low rectocele was no good for the hernia.

Prof. J. KAY JAMIESON described the pelvic fascia as a sling for maintaining the genito-urinary organs in position. There was no anatomical evidence for the existence of a lower uterine segment, but it undoubtedly existed in a certain phase of life. Prof. A. H. DAVIDSON thought that three operations revealed the so-called cardinal ligaments of the uterus: vaginal hysterectomy, the Fothergill operation, and Wertheim's hysterectomy. Mackenrodt's ligaments varied greatly according to whether the uterus was pulled up or down; their division constituted one of the most difficult stages of the Wertheim operation; they had to be divided as near to their insertion as possible. The lower uterine segment arose from the isthmus of the uterus—that part to which the cardinal ligaments were attached. Dr. J. S. QUIN said that the anatomist and the gynaecologist seemed to hold irreconcilable views about the formation of the lower uterine segment. In his opinion high sliding rectocele was always due to a congenital rather than a traumatic hernia. Mr. BETHEL SOLOMONS said that the supports of the uterus were very definite and every ligament helped; section of the pelvis showed that the levator ani muscles and fascia were indirect supports through the vagina. He himself did not do the typical Fothergill operation, but cut the utero-sacral ligaments and sutured them to the front of the cervix. After anterior denudation he brought the bladder pillars, which he believed to be part of the pubo-coccygeus muscle, together in front of the bladder. To cure a prolapse it was not necessary to suture Mackenrodt's ligaments, even though they were the chief supports; in fact, the operation involved danger of including the ureter. For high rectocele he brought together some tissue high up in the vagina.

Prof. O'DONEL BROWNE, in reply, referred to a series of *x*-ray investigations in which markers had been placed in the lower uterine segment at operation and subsequently watched throughout a pregnancy. He believed that the so-called bladder pillars were artificially produced by the dissecting forceps, or by the puckering of stitches.

Amputation and Repair of the Cervix

Dr. EDWARD SOLOMONS, in a paper on the above subject, said that between 1931 and 1939, 302 women had been operated on at Dr. Steevens' Hospital; of these 104 had come to hospital for follow-up examination. The operations performed on them were Emmet's trachelorrhaphy, Schroeder's partial amputation of the cervix, and circular amputation, with a number of Sturndorf amputations. Chromic or tanned catgut was used nearly always. Careful investigation and examination showed that 94 of the women had benefited considerably, and 70 had no discharge after the operation. Backache was the commonest residual symptom, and three patients had a worse discharge after operation than before. Trachelorrhaphy gave the best results for fertility, twenty-three out of a possible thirty having subsequently become pregnant. Seventy-two patients had healed completely, and one had a bad result; the rest showed some degree of ectropion or erosion. No carcinoma was found. Among 115 cases of cervical amputation or repair performed during the last two years there had been four secondary haemorrhages within a fortnight of operation, but no sepsis of any kind.

Dr. J. S. QUIN asked the indications for operation and the history of previous treatment in these cases. He thought that some erosions would respond to being left alone, or treated with very mild caustics. The MASTER OF THE ROTUNDA asked how many of these patients were nulliparous. Dr. A. W. SPAIN thought the number of amputations of the cervix was now much less than formerly; most of these conditions could be cured by cauterizing the cervix. The cautery must be used very lightly, with great care, two or three days after the menstrual period. He was sure there was a place for posterior division in some cases. Prof. A. H. DAVIDSON said that recently he had tended to abandon operation in favour of the electric cautery, unless the cervix was much hypertrophied. He thought the results for pregnancy and labour were better. In some cases the *p*H of the vagina was rather high, and erosions would completely disappear after two or three months, or even weeks, of treatment by acid media. Prof. O'DONEL BROWNE asked the indications for amputation and curettage respectively. Dr. BETHEL

SOLOMONS said that the cautery was suitable only for very early erosions, while a careful trachelorrhaphy or amputation cured nearly every case. Certain pathological conditions predisposed to carcinoma; this made radical treatment almost imperative. He had cured so much sterility by cleaning up and closing posterior division wounds that he thought the operation should be discarded.

Dr. EDWARD SOLOMONS, in reply, said that eighteen of the 302 had been nulliparous and four of these were unmarried. In 60 to 70% some other operation had been performed.

CLINICAL PATHOLOGY AT OXFORD

At a meeting of the Association of Clinical Pathologists on January 4 at Oriel College, Oxford, and the Sir William Dunn School of Pathology, Prof. A. D. GARDNER described the diagnosis of Weil's disease by assay of the agglutinins in the patients' sera. He said that among the collections of cultures of *Leptospira haemorrhagiae* he received on undertaking this work he found a few strains which did not agglutinate with antisera made from the classical strain. In his researches and in the routine diagnostic work antisera made from these aberrant strains were used. Agglutinins appeared in the patient's serum about the sixth day. It was desirable to examine sera taken at the early febrile stage of the disease, though these were difficult to obtain, the clinical diagnosis being made usually only when well-marked jaundice appeared. Several cases of leptospiral meningitis were referred to.

Dr. JOAN TAYLOR spoke of the cultural and serological analysis of cultures from Salmonella infections sent to Oxford from many parts of England. Using the table on page 410 of the *Bulletin of Hygiene*, 1938, Dr. Taylor detailed the various antisera employed, and suggested that these should be called after the accepted group or specific alphabetical and numerical factors rather than after the confusing geographical origin. Craigie's method of obtaining the actively motile bacilli by making them swim through sloppy agar was useful.

Dr. ROBB-SMITH urged that when specimens from cases of adenopathy were obtained for the histologist the whole lymph node should be excised with proper surgical precautions and fixed before being cut across. The novocain should be injected clear of the gland; otherwise structural details of the follicles, sinuses, and medullary tissue might be obscured. Axillary or lower cervical glands were to be preferred. He surveyed the differential diagnosis of cases of widespread adenopathy, emphasizing the importance of using reticulin stains for this purpose.

Dr. C. L. COPE discussed the value of estimating pregnandiol in the urine. Absence of pregnandiol after a threatened miscarriage strongly suggested that the foetus was dead. The test was also of value in the diagnosis of deciduoma malignum, since, unlike the Aschheim-Zondek reaction, it was constantly negative in this condition. Captain HANSON described the determination in the blood of the free forms of sulphanilamide, sulphapyridine, and sulphathiazole after the administration of these drugs, the aim being to assess the optimum dosage in various clinical conditions. The conjugated forms of the drugs in the blood were not therapeutically active. It was difficult to decide an optimum concentration, for the administration of the same dose of the drug might on different occasions give different results.

An informal discussion on the future of clinical pathology was opened by Dr. A. F. S. SLADDEN. The outlines of a scheme for the regionalization of laboratory services in the Provinces had previously been discussed by the association, and there was general agreement on the advisability of a scheme in which pathologists would become officers of a regional pathological service closely allied to the regional hospital service proposed in the Nuffield scheme. It was considered to be essential that clinical pathologists should work in hospital laboratories in close touch with patients, but increasing specialization in clinical pathology made it also important that they should be able to refer the more specialized work to a central laboratory. Such a plan would ensure constant diffusion of the latest information and methods, thus acting as a stimulus to research and progress.

Correspondence

The Transfusion Problem

SIR,—Dr. Peyton Rous has kindly called my attention to your leading article (November 2, 1940, p. 597) on "The Transfusion Problem." It contains the statement that stored blood, despite the addition of glucose, cannot be kept beyond a fortnight for average use. Since the limits of storage are of vital importance in military medicine this subject should be elucidated. Criteria which might be used to establish limits of storage are the quantity of free haemoglobin in the plasma, the age at which the leucocytes or platelets disappear, the titre of prothrombin, and perhaps a dozen others. Most workers have tacitly accepted the amount of haemolysis occurring during storage as the most important limiting factor. Unfortunately the renal threshold for haemoglobin varies considerably in different individuals, so that the exact amount of haemoglobin which is safe to give cannot be stated with accuracy. We are left, then, with the task of determining the incidence of reactions in recipients receiving bloods of various ages.

In reading the numerous recent British publications on stored blood it is evident that most workers are adding relatively small amounts of glucose, so that the concentration in the blood mixture is 0.5 to 1%. This is probably done in the interests of compactness. It should be noted, however, that the original mixture of Rous and Turner contained a 3% concentration of the sugar. The modification which we are using has a similar value. From studies by Hardin, Harris, Bell, and me, which are not yet published, we concluded that the optimum concentration of glucose to inhibit haemolysis was 3% or more. To attain such a value blood can be mixed with a large volume of 5.4% glucose or a smaller volume of a more concentrated solution. The latter procedure is dangerous, however, since it results in hypertonic plasma and erythrocyte contents, so that stored cells may rupture when contact is made with the isotonic plasma of the recipient.

It is our practice to add 500 c.cm. of blood to an ice-cold mixture of 650 c.cm. of 5.4% glucose in water and 100 c.cm. of 3.2% dihydric sodium citrate in water. The blood mixture is then immediately placed in the refrigerator (DeGowin, E. L., Harris, J. E., and Plass, E. D., *J. Amer. med. Ass.*, 1940, **114**, 850). The blood-glucose-citrate is used for routine hospital transfusions with an arbitrary thirty-day limit of storage. Our first statistical study on transfusion reactions from such a practice were published in this *Journal* (DeGowin, E. L., and Hardin, R. C., 1940, **2**, 1) in the hope of calling attention to the fact that blood stored for thirty days in this preservative was perfectly safe for transfusion. At the time of publication sufficient statistics on older bloods had not been accumulated to be impressive. Up to May 1, 1940, we had given 209 transfusions with bloods stored from fifteen to thirty-eight days with only three reactions: one with chills only, one with chills and fever, and one with urticaria. This is an incidence of 1.4%. There were no patients with haemoglobinuria. On December 1, 1940, we had given over 2,000 transfusions of the blood-glucose-citrate with a thirty-day limit of storage and have found the practice perfectly safe. The oldest blood transfused was given in the course of an experiment on transportation. The blood was collected in the glucose-citrate mixture and stored for fifteen days. It was then shipped in ice by transport airplane from Iowa City to Oakland, California, and back, a flying distance of 3,539 miles. The mixture was again stored, and transfused without reaction on the forty-fifth day after collection.

Since the administration of stored blood is frequently an emergency measure in the treatment of shock, we believe much valuable time is lost and excess equipment is required in prewarming the mixture to body temperature. Prof. S. L. Baker (*Lancet*, 1937, **1**, 1390) was one of the first to report that blood transfusions given at room temperature did not result in an increased incidence of reactions. Drs. Hardin, Swanson, and I (*J. Amer. med. Ass.*, 1940, **114**, 859) transfused patients with bloods taken directly from the refrigerator without

producing reactions. The blood mixture was injected into the median basilic vein at such a temperature that the cephalic vein of the same arm felt cold to the touch, but the recipients had no discomfort. In our series of over 4,000 transfusions we have been unable to find any evidence to support the view that the blood should be warmed during administration.—I am, etc.,

The State University of Iowa, Iowa City, Dec. 31. ELMER L. DEGOWIN.

Treatment of Carcinoma of the Cervix

SIR,—In reply to Mr. Victor Bonney's letter (January 25, p. 133), I readily admit that I was unwise to make any attempt in the tables in my Bradshaw Lecture to indicate any possible "staging" of the operation cases of carcinoma of the cervix, but I did explain in the text that operators had not separated their cases into stages on the lines of the League of Nations classification. Moreover, such a division of the operation cases into stages was not material to the comparison I made or to the conclusions drawn. I should be sorry to give any false impression of Mr. Bonney's achievement, which is all the more remarkable when we learn from him that the greater number of his gland-free cases would have been radiologically classified as belonging to Stage III, for that stage comprises cases presenting one or other of the following clinical features:

(*a*) Nodular infiltration of the parametria on one or both sides, extending to the wall of the pelvis, with limited mobility of the uterus or massive infiltration of one parametrium with fixation of the uterus.

(*b*) More or less superficial infiltration of a large part of the vagina, with a mobile uterus.

(*c*) Isolated metastases in the pelvic glands, with a relatively small primary growth.

(*d*) Isolated metastases in the lower part of the vagina.

The comparison which I made between the results of operation and radiation was based on the figures for all the first three stages, excluding only Stage IV, which comprises the cases that are certainly inoperable. Taking as operable all the Stage III cases in the radiological group gave a distinct advantage to surgery in the comparison.

In quoting Bonney's figures I took them as published, except that I corrected the arithmetical calculation of his five-year freedom rate. The correct rate for 142 five-year survivors out of 366 cases is 38.8% and not 40% as stated by Bonney (*Trans. med. Soc. Lond.*, 1934, **57**, 196).

I gave most careful consideration to the problem, and must leave the figures to speak for themselves as to whether my conclusions were justified. After all, when there are rival claims it is the profession as a whole which must be convinced of the best method of treatment, for it is the general practitioner who advises the patient where to seek expert assistance. The results of the two methods of treatment for carcinoma of the cervix convinced me that the advocates of radiation therapy had proved their case, even without taking into consideration the primary mortality of the radical operation, which may be as high as 20% in a surgeon's first hundred cases. A comparison of the results obtained by operation or radiation was made by Prof. Fletcher Shaw and Prof. Dougal in cases which they treated themselves, and their conclusions were the same as mine (*Surg. Gynec. Obstet.*, February 15, 1937, **64**). A further study of the results obtained at the Middlesex Hospital is about to be published by two of my colleagues.—I am, etc.,

London, W.1, Jan. 27. ALFRED WEBB-JOHNSON.

Haemorrhagic States with Snake Venom and Lecithin

SIR,—We must plead the preoccupations of the present emergency as our excuse for not having submitted the full-dress review of our studies of the coagulant action of venom–lecithin mixtures to which Dr. H. W. Fullerton is entitled, in view of his own interesting work on the action of Russell-viper venom in accelerating coagulation.[1] [2] Our observations on the inverse relation between the adjuvant action of lecithin and the number and efficiency of the platelets appeared to show something novel, and we therefore reported them first. As soon as time permits we shall publish the results of comparative studies of the various reagents used for the accelerated clotting reaction in experimental jaundice in animals and spontaneous jaundice in man. These indicate in our opinion that the venom–lecithin mixture is preferable for the determination of prothrombin times, for with venom alone anomalous results are sometimes obtained, more particularly during treatment by vitamin K. In any event it is short-sighted to think only in terms of prothrombin or to limit oneself to accelerating the clotting reaction with venom alone. When one has gone to the trouble of getting oxalated plasma and a water-bath, it is little extra work to measure the clotting times of recalcified plasma alone (Howell), plasma plus venom (Fullerton), and plasma plus venom and lecithin (Hobson and Witts). In this way three separate types of clotting defect can be distinguished—thrombokinase (haemophilia), prothrombin (jaundice), and lecithin factor (purpura haemorrhagica).

All the Russell-viper venoms we have tested show the peak of their activity at a dilution between 1/10,000 and 1/20,000, presumably because inhibitory or lytic factors come into play at higher concentrations. Although samples of the same batch are identical, different batches vary in activity a good deal. We have preferred not to work at the maximum speed of the best venoms, partly on grounds of economy and partly because it is wise not to set the level too high if successive batches are to be standardized to give identical values. Our best venom–lecithin mixtures will give accelerated clotting times of six seconds, but so great a speed is not an unmixed blessing to the observer. We have planned to make a series of statistical observations to determine the optimum activity of reagent for the purpose of the test, and in this respect it is a helpful coincidence that the venom–lecithin reagent we have chosen for these preliminary observations gives the same normal values as the acetone-dried brain extract which Quick now uses.—We are, etc.,

L. J. WITTS.
Oxford, Jan. 20. FELICITY C. G. HOBSON.

Immunization against Infection in the Army

SIR,—I was interested on reading the extract from the Harben Lectures by Lieut.-Col. H. J. Bensted (January 4, p. 187). During the last quarter of 1896 I was one of a batch of thirteen surgeons on probation for the Army Medical Service who passed the competitive examination held in London and reported for training at Netley. To all of us the lectures on bacteriology by Almroth Wright were a revelation and an inspiration. The practical course supervised by him and his assistant, Leishman, was the high-light of the whole course of training then in vogue. It aroused in us such trust and enthusiasm that I think the whole of my batch volunteered to be inoculated with typhoid vaccine. Each one had his serum agglutination titre tested before and again some weeks later. The results were uniformly satisfactory. During the summer of 1898 I served in the Nile campaign, which ended in the fall of Omdurman and the reoccupation of Khartum. The main part of the force consisted of two brigades of four regiments of British infantry. Many of these when advancing on Omdurman after the preliminary phase are said to have drunk and refilled their water bottles from a badly polluted collection of water in the Khor Shambat. The result was a severe outbreak of typhoid fever, and I myself was in charge of a great number, first in mud barracks at Darmate and later in the Citadel Hospital, Cairo. I have never seen such a virulent type of the disease in all my subsequent twelve years' service in India. A man would report sick looking as if he was in the first stage of an attack of ague. He would often be dead in seven days or less. Post-mortem would reveal an enlarged spleen and Peyer's patches uniformly swollen and inflamed, no ulceration having yet commenced. In many cases portions of the spleen were sent to the laboratory of Prof. Rupper, who cultivated *B. typhosus* from all specimens.

While serving in Peshawar (1898–1904) the incidence of typhoid was high, as it was all over India among the British troops. Again in Mhow in 1905–6 there was a serious outbreak, and it was only in the latter year that I saw any serious

The successful treatment of

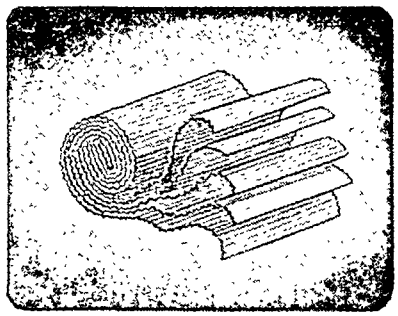
FIBROSITIS AND CERTAIN CASES OF RHEUMATISM

with

NOVUTOX INJECTIONS

A mass of evidence has accumulated to show that the treatment of Fibrositis and certain cases of Rheumatism with Novutox injections provides restoration of function with immediate relief from pain, and in the majority of cases, an early recovery.

Novutox, which is a self-sterilising local anaesthetic, is prepared by a special process, and the preparation contains, in extreme dilution, certain highly complex quinine derivatives. Due to treatment by this process, Novutox solutions have a remarkable chemo-therapeutic action and also unique antiseptic properties which, associated with extremely low toxicity, are held to account for the very satisfactory results achieved with the preparation in the treatment of Fibrositis and certain cases of Rheumatism.



In an article entitled "Muscular Rheumatism—Local Injection Treatment as a Means of Rapid Restoration of Function," published in the "British Medical Journal," 10.8.40, page 183, the author describes the treatment of a number of typical cases of Fibrositis, etc., in different part of the body and *in all cases* immediate relief was obtained following injections of Novutox. During an attack of lumbago suffered by himself the author found one injection abolished intense pain and restored function within a matter of minutes. He also gives useful detailed information of the technique employed for the various sites of the body.

Interested members of the medical profession are invited to write for a copy of "Notes on the Treatment of Fibrositis and Recent Injuries."

NOVUTOX is available in:
2 c.c. and 50 c.c. AMPOULES. 2-oz. BOTTLES and CARTRIDGES (standard sizes).

Manufactured by:

PHARMACEUTICAL MANUFACTURING CO., LTD.,
The Laboratories, PITTVILLE CIRCUS RD., CHELTENHAM, Glos.

Throat irritation

Five protective layers go to make up the filter tip of every du Maurier cigarette. Three layers of white vegetable tissue with alternate layers of fine cellulose protect the membranes from the irritant action of pyridine bases and other non-volatile bodies. Although no shred of tobacco can pass the lips and no unfiltered smoke can impinge on the tongue, the du Maurier tip allows the full flavour and fragrance of finely selected tobacco to pass unimpaired.

du MAURIER

the perfect cigarette with the exclusive filter tip

CORK TIP IN THE RED BOX : PLAIN TIP IN THE BLUE BOX

effort at immunization. Even then it merely consisted in segregating the reliefs arriving for British units and inoculating the men before they were admitted to the regular barracks. Why these men were not inoculated before embarkation or during the voyage out, a period of twenty-one days, is a mystery.

The success of more universal inoculation of troops proceeding to India in later years has been remarkable. However, the crucial test came during the war of 1914–18, in which I also served. The success of T.A.B. inoculation was overwhelming, the incidence of typhoid and paratyphoid being trifling in our forces, whereas in the French forces, I believe, some 200,000 cases occurred during the first year. The debt which the whole world owes to Sir Almroth Wright in this sphere alone is immense. As one of his disciples and an original volunteer, this small tribute of homage is offered.—I am, etc.,

W. E. HUDLESTON,
Edinburgh, Jan. 17. Colonel, A.M.S. (ret.)

Medical Planning Commission

SIR,—Like several of your correspondents in the *Journal* of January 25 (p. 131) I am seriously disturbed by the unrepresentative character of the Commission. The sixty-seven members include thirty-six consultants and specialists, nineteen general practitioners, and twelve others from various groups. But not only is the number of general practitioners disproportionately small, but even that small number is badly balanced. Of the nineteen, fifteen are from large urban areas, two from semi-rural, and two only from rural districts. Moreover, from the large number of general practitioners engaged in contract practice in colliery areas only one practitioner has been selected, and he is from Scotland, where the conditions of service and remuneration are fairly satisfactory. No possible exception could, I think, be taken to those general practitioners who have been selected, but the number of rural practitioners should be largely augmented and representation given to the colliery medical officers in the North and Midlands of England and in South Wales. I do not think urban practitioners can do justice to the special problems of rural and colliery practice, not from lack of good will but from lack of knowledge.

When first made aware of the proposed membership, I endeavoured to get it amended, but was met by the statement that the Council could not see its way to increase the number of members, already far too large. It is true that the Commission has the power to co-opt, but can this be done adequately without still further increasing an already cumbrous and almost unmanageable number?

The difficulties of this Commission are likely to be very great. Imagine a body of sixty-seven members trying to co-ordinate and dovetail the reports of its committees, some of which, if not actually antagonistic, may well be not altogether in harmony. Moreover, in practice, the balance of representation may be still further worsened by the great difficulties of travel from the Provinces at present, and yet the discussions will be vital to us all. Take one instance, the point raised by Mr. P. L. Giuseppi (January 18, p. 97)—a State medical service—what can the Commission say to that at the present juncture? For years past, as I see it, the demand for a State medical service has been becoming more and more clamant on the part of the younger members of the profession. A large number of young and middle-aged practitioners are now in a State medical service, and the list will probably be doubled before peace comes. What will be the attitude of these men to a State service when they return to civil life? Who can say? What can the Commission say? And yet, before it plans, it must have some idea on what basis it shall plan. We cannot build until we know something of the foundation on which we propose to build. Is it to be something not greatly altered from the present system, or is it to be something radically different? To my thinking, this is the vital issue to which the Commission should apply itself before any rational planning can be undertaken.—I am, etc.,

Ashover, Jan. 25. H. W. POOLER.

SIR,—Every member of the medical profession must be vitally interested in the work to be undertaken by the Medical Planning Commission recently appointed by the B.M.A. The terms of reference are necessarily vague; but the outcome will, I take it, be a scheme for the medical servicing of this country at the conclusion of the present war.

It is certain that any post-war Government will insist on radical changes in the methods hitherto adopted for giving medical service to the public. Few if any of us would attempt to argue that considerable changes are not essential. It is almost equally certain that the Government will consider sympathetically any scheme evolved by the medical profession, provided the benefits accruing to the public are clearly shown. In the past, to certain sections of political thought, we have been suspect of self-interest in the various plans we have proposed.

Clearly it is of paramount importance for the success of any scheme that it must have the whole-hearted backing of the vast majority of the profession. Such support can honestly be given only if everyone concerned in its working has previously examined the scheme searchingly and tested its merits against those of many other possible plans. A large number of practitioners consider that a full-time State service is not only inevitable but desirable; many would view such a change as a catastrophe. The preservation of full free choice of doctor and the personal relationship between patient and doctor seems to many of us to be of the utmost importance—especially from the patient's point of view. The avoidance of a multiplicity of paper work, the inevitable tendency to a lessening of initiative (promotion on "the Services" will not prevent this), and very many other adverse features of a purely State service suggest the desirability of some other scheme.

Dr. Arthur Beauchamp (Jan. 18, p. 96) congratulates the Executive Committee and the Council on the personnel of the Medical Planning Commission. The outstanding professional status of the individual members is beyond question; in fact a more distinguished body could not have been selected. It is, however, of great importance that the personnel of a Commission elected to investigate the most vital problem ever raised in medical politics should be thoroughly representative of the entire profession. The personnel of this Commission shows an utter lack of proportion as regards both (1) age groups and (2) avocation. An approximate analysis of the personnel shows:

1. Out of fifty-seven names published (ten have still to be appointed), fifty commenced medicine prior to the end of the last war, only seven commenced medicine after the end of the last war (that is, 87.7% to 12.3%), 62 are over 50 years of age.

2. *Avocation.*—Presuming that the ten members still to be appointed by the Royal Colleges, etc., will fall under the consultant group, we have: consultants, academic, public health, etc.=47 members; general practitioners=20 members—that is, 70% to 30%. Surely neither such a high age-group preponderance nor such a low percentage of general practitioners can be regarded as being in any way fairly representative of the profession.

The only way to obtain a really representative view from the profession is ultimately to secure the views of the practitioners in each area. By this I do not mean merely the various Divisions and Branches of the B.M.A., but all the practitioners (B.M.A. or non-B.M.A.; general practitioner, consultant, public health officer, etc.) in each area. These meetings can easily be convened by the good offices of each local secretary of the Association.

Not one of us will have any right to criticize the future findings of the Medical Planning Commission unless he has first whole-heartedly examined all the possibilities for himself. Nor have we any right to expect the Commission to wrestle with its enormous task unless we have all given our considered opinions from time to time. It would be unfair to the Commission and unsatisfactory to ourselves to allow it to spend untold labour in producing a finished, or even a semi-finished, scheme which would then be put up for possible criticism and amendment by the Divisions and Branches.

I suggest that the Commission be asked first to draw up a framework of possible reorganization of the medical services. This should embody the main agreed points, and also the views of the minority on any point. This preliminary report could then be sent to the local secretaries of Divisions and Branches, each of whom would call a meeting (or a series of meetings) of

all the practitioners in his area. The Commission's framework would serve as a starting point; and each area would then fill in the structure according to its own views.

These local schemes would be sent to the secretary of the Commission, who would have them summarized, and would then return a composite summary to each local secretary. Having given full consideration to the new data thus obtained, each "area of practitioners" would submit its findings to the Planning Commission. From this point the Commission, with access to outside experts (Ministry of Health, etc.), would be in a position to construct a definite scheme truly representative of the views of the entire profession. The Services members would be consulted through the appropriate channels.

Eventually a concrete plan would be submitted once again to the various areas for amendment and final touching-up. The conclusions thereafter rendered to the Commission should enable it to draw up a final scheme, which would require very little discussion by the profession.

In dealing with such a comprehensive matter, so vital to every branch of medical service and to the country, the method of procedure suggested here cannot fairly be considered cumbersome. Even in these days of stress time must be found in order to construct a successful scheme. To hasten a decision, to fail in consulting every member of the profession, would be to invite disaster on a noble project.—I am, etc.,

Bath, Jan. 20. CHARLES R. GIBSON.

SIR,—Of sixty-seven names, forty are of consultants, eight are of paid officials, the other nineteen are not definitely stated to depend on general practice alone for their living. What do the general practitioners of the country think about this? How will they voice their views; how protect their vital interests?—I am, etc.,

Bradford, Jan. 4. THOMAS SAVAGE.

Medicine in a Changing World

SIR,—To me, and I expect to most of us, Sir John Orr's address to the Leeds Division (January 18, p. 73) reads as most restrained and reasonable and free from any suspicion of entering into party politics—unless his opinion that poverty had something to do with malnutrition was in your eyes entering into that forbidden field. But that was accepted by every speaker at the B.M.A. Conference on Malnutrition in April, 1939, and I remember hearing Mr. L. S. Amery going further and saying that a "great many" industries simply "could not" (not "would not") "pay sufficiently high wages to provide adequate nourishment for a family with three children." There would not therefore appear any cause for you to use this Leeds address as an occasion to give us a lecture (p. 91) on allowing our "political emotions" to warp our judgment and suggest that this had happened to Sir John. You continue, however, "This is perhaps well illustrated by reference to the subject of Sir John Orr's lecture," and your leader on this occasion makes as little contact with fact as did that unfortunate one on shelters.

Anyhow it is hoped that you will let us have another leader in which you will tell us just what your qualifications are which entitled you to lecture us on how we are to live our lives and why your remark about members allying themselves with one or other of the political parties "somewhat ostentatiously" is not just impertinence. Perhaps a prize might be offered to anyone guessing correctly what party you had in mind. It was, however, with some relief that one read that "a doctor may cast his vote as freely as any other man," for this presumably includes members of the B.M.A., although this is not made quite clear. A charming chance led you to introduce the old tag, "The cobbler must stick to his last."—I am, etc.,

Grimsby, Jan. 20. S. W. SWINDELLS.

SIR,—I think you are right in saying (January 18, p. 91) that medical men as such should not segregate themselves into political groups. That is true; since politics is not really the best kind of sociology. One who proposes to cure the world's ills by politics—that is, polemics—is like the doctor who proposes to stamp out disease by multiplying bottles of medicine. Politics and pills are at best stop-gaps or temporary expedients. True hygiene, medical and social, should make such things unnecessary. These and other parallels are very valuable, and I hold that every intelligent doctor is, or should be, a sociologist. Also, as you yourself add, "The medical profession has within its numbers those who, more than any other group of men and women, are competent to make a statement on the physiological and psychological needs of human society." I further maintain (and could prove) that this holds of the general practitioner, and, above all, of the country practitioner with his all-round field of observation and action, more than of the specialist with his arbitrarily restricted *Fach*. The truth is that in a proper system of medical services the specialists should be subordinate or ancillary to the general practitioner, not his masters as at present. That the G.P. does not always, or even generally, take advantage of his unique opportunities and thus tends to evade his social responsibilities is due to various causes which I shall not attempt to enumerate here. The facts are, however, I am sure, as stated.—I am, etc.,

Helmsley, Yorkshire, Jan. 26. A. J. BROCK.

Trends in Nutrition

SIR,—In the lecture by Sir John Boyd Orr (January 18, p. 73) many statements are made which have already been challenged by me (vide, e.g., *Edin. med. J.*, 1940, **47**, 425). There is one, however, which I have not had the opportunity of dealing with before. On page 74 it is stated: "About fifteen years ago the subject [the influence of nutrition on susceptibility to infectious disease] was investigated by a group of workers associated with the Rowett Institute, including Prof. Mackie and the late Prof. J. J. R. McLeod. In experiments with farm animals it was found that certain immunological reactions were considerably affected by the nature of the ration."

The context shows that it is to be inferred that the more adequate the diet the greater in amount are the antibodies produced and the less the susceptibility to infectious disease. Apart from the misuse here as elsewhere in the article of the word "nutrition," it has to be stated without reservation that no such conclusion could warrantably be drawn from the results of these investigations as they are recorded in the *Lancet* of May, 1931 (**1**, No. 5622) and the *British Journal of Experimental Pathology*, 1932, **13**, 328.

Since they had been cited by him in published articles and otherwise on previous occasions in support of his present thesis, I naturally expected mention to be made here of certain other observations on similar lines conducted by himself and subordinates during this same period. As a consequence of these it was alleged that the addition of a mineral supplement (containing a high proportion of calcium) to a ration of bran and barley conferred on the rabbits receiving it protection from the effects of an intravenous injection of human tubercle bacilli. I am able to state quite categorically from the protocols and other highly pertinent details, both of which I possess, that this claim should never have been made.—I am, etc.,

Aberdeen, Jan. 18. J. P. MCGOWAN.

SIR,—It was with profound horror that I read one sentence in Sir John Boyd Orr's otherwise fine article, "Trends in Nutrition" (January 18, p. 73), in which he said: "The Canadian Medical Association has published an excellent booklet showing the kind of diet needed for different families and the cost, and has thereby *adjusted propaganda to economic realities*" (my italics). Stated in less "diplomatic" language this would read: "The Canadian Medical Association has published an excellent booklet showing not only the kind of diet needed for different families, but also the cost, thereby instructing us that we must popularize diets in relation to their cost and not to their suitability, for there are many people without sufficient money with which to purchase the best." Dietetic realities essential for health are to be subservient to "economic realities."

The tragedy of the statement lies not only in the fact that we are directed to prostitute our guardianship of the people's health but in that it is the product of old-fashioned thinking. The fundamentals of the sentence are, first, that there are certain dietetic needs which are known to exist. They are necessary for the health of the body, which was made by God and not by man. No man can lessen those needs by suggestions, laws, regulations, high cost, or any other means; they are absolute. Every fresh research shows that our know-

ledge of them is incomplete. Every advance of knowledge reveals further needs, not reduced requirements. Economic realities, on the other hand, are statements about supply, effective (monetary) demand, purchasing power, credit, and so on, put out by economic experts as being fundamental implications of inexorable economic laws. But, be it noted, all economic "laws" are man-made and are controllable and alterable by man.

It will be recalled that "the sabbath (which used to be governed by many laws) was made for man, and not man for the sabbath." In precisely the same way economic laws were made for man and not man for the laws. They were originated to facilitate man's life and private and commercial exchanges, and to simplify barter. That they have been perverted into a means of power, of control of all man's activities and even of his health, is no justification for statements such as Sir John's. It is our privilege and our duty to resist such evils and to insist that man shall be able to live a full life.

Lest it be thought that my words are merely the scribbling of some obscure person let me quote those of Lord Horder in an article in the *Sunday Times*. It will be seen that I am in the company of the great ones of the profession. "If I were made a Dictator for the purpose of doing only one thing as a contribution to the Good Life, I know what I would do. I would put the Ministers of Health, Agriculture, and Transport into a room together and keep them there until they had settled the problems of food production and food distribution in this country. *The only person* I would allow them to send for to help in their deliberations would be the *Governor of the Bank of England*" (my italics).—I am, sir,

Manchester, Jan. 24. W. SYLE CREER.

Working of A.R.P. and First-aid Services

SIR,—We have had in your columns a most interesting correspondence on equipment, etc., for use in air raids. I have been wondering for some time if correspondence or articles could not be introduced on a similar line but embracing matters on a much larger and more general scale.

It would be of the utmost value and at the same time of the greatest importance if the views of the medical officers of health and general practitioners and hospital officers could be obtained as regards the working of the A.R.P. and First Aid Services. Those who have had the fortune—or should I say misfortune?—to have actual experiences in this matter could in this way give their findings for the benefit of those who have not been in an area attacked. I feel that there must be many minor modifications in the original plans and many errors which have had to be corrected. It appears to me to be a great pity that these errors should have to be repeated in all areas, whereas were those who had had experience—and there must be many now—to give their views either in the form of correspondence or a series of articles all this could be saved.

I have been much surprised that the Ministry has not obtained such views from a questionary to medical officers of health and then informed others of the modifications found necessary in the light of actual events. I feel that there must be many slight changes which would improve such services in the area of which I am in charge, yet I cannot introduce them for lack of practical experience, and there must be many more in a similar position.—I am, etc.,

Jan. 19. R. E. JOHNSON, M.B., Ch.B.

The Mobile Unit in Action

SIR,—Dr. E. K. Macdonald (January 4, p. 30) states that it is difficult to envisage any situation in a city where a mobile unit can prove of more value than the ordinary fixed post. May I cite this instance:

The procedure our controls adopt now is to call out, first, the medical officer and sister with stretcher car to the incident. Should the medical officer see fit to call out the unit he does so. This was the procedure adopted one Sunday night recently. On arrival at the site I found high explosives had been dropped in neighbouring streets, in all of which the houses were more or less completely demolished. Near by one crater five people were entombed and required my attention. While engaged here, four messages came from adjoining streets for help. I decided to call out the unit. Once this arrived I dispatched a nurse to each street armed with *hypodermic syringe, morphine, coramine*, and dressings. The two men in the shift plus the driver acted as liaisons, fetching hot bottles and blankets to various cases. The nurses acted admirably, not only in relieving pain but in standing by the casualty for hours, and keeping torn tissues clean and free from falling mortar and debris, and administering restoratives. One case is worthy of mention—that of a young man with two-thirds of scalp avulsed. A nurse stood by this man for four hours; whenever the rescue party rested she stepped in and swabbed away debris from scalp and applied fresh pads. Surely this is not a singular case (now doing well and surely saved from sepsis by this nurse).

It is interesting to read various reports for and against the mobile units, each varying according to various doctors' experiences. Dr. J. J. Cremin's experiences at Coventry made him question (December 14, p. 847) the utility of mobile units, particularly when his unit was destroyed. Granted that a mobile unit exposes itself to great risks, this is no argument for its abolition. The crux of the question is this: Is there a need for immediate skilled treatment at this site of an incident prior to removal to hospital or is there not? Speaking as a medical officer of a mobile unit in perhaps the second worst-struck borough in London, I say there certainly is a need.

How many seriously wounded trapped cases did Dr. Cremin leave behind? Are there not trapped wounded cases at most incidents which cannot be whipped off to hospital? I agree that it is not wise to call out the whole unit in every case, but the procedure adopted here obviates the unit going to the wrong or smaller incident. These units cost £3,000 a year in trained personnel alone. Surely this is not going to be wasted. Rather would I advocate more use being made of them, but at the discretion of a medical officer at the site of the trouble rather than at the discretion of Controls, who are instructed by the local warden, with his multitudinous duties, which incidentally have never yet been defined.

May I state here my admiration of all branches of A.R.P. organization and the excellent work they are doing, but who is the "boss" at an incident? I find in my experience great need for co-ordination and leadership.

I should like to state in closing this letter that as a combatant officer in the last war I owe my life to first aid in the field—I am, etc.,

J. F. MACKIE.

Jan. 20. M.O. Mobile Unit.

SIR,—We should like to refer to, and constructively criticize, some points which have been brought to notice in the letters of your correspondents on this matter.

During the months of September, October, and November, 1940, the two Paddington Mobile Units have been in action many times and dealt with 107 casualties. In only three of these incidents did a complete unit with van turn out. On twenty-two occasions the team consisted of a medical officer, two nurses, and a stretcher-bearer whose duties include liaison, besides the driver of the car. The car was uncomfortably full when appliances were added to personnel.

The chief difficulty experienced was to get to the scene early enough. In Paddington the "Blitz" has not been nearly so intense as it was, for instance, at Coventry. It transpired that the wardens first on the spot were in the habit of asking Control primarily for a stretcher party. These men are most efficient and keen; but zeal has sometimes outrun discretion in their endeavour to save time. The presence of a mobile unit (or part of it) with its medical officer is nearly always necessary; the unit should work, not in competition, but in unison with the stretcher party, and they should be called out simultaneously. Often the mobile unit has not been ordered out because the wardens have not asked for a medical officer or, if asked for, it has been so long after the incident occurred that nearly all the casualties have already been dealt with, and the medical officer is only required to administer morphine or a general anaesthetic, or to certify death. As speed is the essence of success in our work, procedures of an operative nature, however tempting, are not, and should not be, undertaken unless, of course, life is in immediate danger. The administration of CO_2 or CO_2–oxygen has been called for.

Although the "Blitz" has eased up in London during the last six weeks, and the utility of mobile units has been questioned, we are solemnly warned—and the warning comes from those who are in a position to know—to expect further and more serious trouble during the next ninety days.—We are, etc.,

R. GALWAY MURRAY.
S. CROWN.

London, W.2, Jan. 20. M.O.s i/c Mobile Units.

The Problem of the Shelters

SIR,—With reference to Prof. J. R. Marrack's letter (January 11, p. 61), the remark of mine regarding drainage problems to which he draws attention related to Haldane's deep shelters as distinct from the surface type. With regard to his final remark that the labour and material necessary for effective indoor shelters would be prohibitive, it would be a grave disservice to the community for this to be allowed to pass unquestioned. The fact that in a great many cases these could be provided at a cost of £4 per head seated, or £8 per head in sleeping bunks, is some indication that the labour and material involved would be much less than Prof. Marrack fears.—I am, etc.,

Rugeley, Staffs, Jan. 17. H. MASON.

Pregnant Women in Target Areas

SIR,—As a practising obstetrician I view with grave concern the failure of the local authorities to evacuate pregnant women from the large maternity units under their care in areas which are well known to be likely targets for enemy aerial attack. In many cases these hospitals have already suffered damage and casualties among the patients; yet no effort has been made to evacuate the patients or even to move them to the periphery of the city. I fear that the attitude of the Ministry of Health in preventing local authorities from establishing maternity units in the country outside the city boundaries is being seized upon and made an excuse by those who are opposed to evacuation.

To carry out systematic midwifery and deal with abnormal cases under the constant threat of aerial attack is exceedingly difficult, nor can the training of pupil midwives be satisfactorily carried out. Despite this, some of our maternity hospitals are being booked with almost the same number of cases as in peacetime, and the Central Midwives Board regulations for training remain unaltered.

During aerial activity there are few more to be pitied than the full-time pregnant woman, and none more worthy of our consideration. I trust that some action may be taken while there is yet time.—I am, etc.,

Jan. 20. A MIDLAND PRACTITIONER.

Dyspepsia in the Army

SIR,—May I put forward these suggestions to supplement Mr. Reginald T. Payne and Dr. Charles Newman's "Interim Report on Dyspepsia in the Army" (December 14, 1940, p. 819). (1) How many of these cases from France indulged in the raw wines of France, obtainable at the estaminets, as compared with beer drunk here? (2) What further steps can be taken for men proceeding abroad to ensure all bad teeth are extracted, and where necessary new dentures provided before they are allowed to embark? (3) Could not some means be devised whereby the records we so laboriously kept of panel patients in peacetime be made available to recruiting medical boards. Would it not save the country a great deal of money and save the medical services much valuable time?—I am, etc.,

C. C. H. CHAVASSE.

Malaria Therapy in General Paralysis

SIR,—The recent death of Prof. Julius Wagner-Jauregg at the age of 83 years calls to mind the fact that the method of treating general paralysis by the inoculation of benign tertian malaria, which constitutes the late Professor's most notable contribution to clinical medicine, is still largely empirical, although this circumstance does not detract from its undoubted value as a therapeutic measure.

It is generally believed that the beneficial results of malaria therapy in general paralysis and certain other diseases of the nervous system are attributable to the direct or indirect effects of suddenly induced pyrexia upon the *materies morbi* or its toxin. In general support of this view I am tempted to record my personal reaction to a primary attack of benign tertian malaria deliberately acquired, *not* as a therapeutic measure but in the course of an experiment. During the hot stage the mental faculties were exceptionally clear, the imagination vivid, and several ideas regarding work then in progress flashed through the mind, some of which were actually followed up later.

I would not have ventured to record so trivial an incident lest I be charged with "presuming on an ague's privilege," but this does not apply to the account given by Wallace of how, after many years' study, he came to formulate, independently of Darwin, the theory of natural selection. Speaking of the year 1858, when he was at Ternate, Malaya, Wallace, in a letter dated December 3, 1887, reproduced at page 189 of the *Life of Charles Darwin* (1902) by his son Francis Darwin, states: "I was lying on my bed (no hammocks in the East) in the hot fit of intermittent fever, when the idea suddenly came to me. I thought it almost all out before the fit was over, and the moment I got up began to write it down, and I believe finished the first draft the next day." In a footnote the editor states that in another and later account of the same incident Wallace speaks of the "cold fit," instead of the "hot fit," of his ague attack, but doubtless the earlier account is correct, since the sole preoccupation during the cold stage is how to become warm.

The above facts lead one to wonder whether the beneficial effects of malaria therapy in general paralysis may not be attributable, in part at least, not so much to pyrexia, *qua* pyrexia, but to the blood supply of damaged cerebral tissue being permanently improved by the opening up of blocked capillaries during the hot stage.—I am, etc.,

C. A. GILL,
Reigate, Jan. 13. Colonel, I.M.S. (ret.).

Electrical Convulsant Therapy

SIR,—Our attention has been drawn to an article by Dr. E. B. Strauss and Mr. A. MacPhail in your issue of December 7 on convulsion therapy.

As manufacturers of convulsion therapy apparatus to the design of Mr. W. Grey Walter we would like to correct the statement at the foot of page 780 that he uses direct measuring current for determining the patient's head resistance. In our apparatus the resistance is measured with alternating potential applied to the electrodes, as in the original apparatus used by Fleming, Golla, and Walter. A descriptive booklet on the Ediswan apparatus is attached, and for the benefit of inquirers we would add that the price is £40 complete, net. Orders are being executed in rotation, owing to the difficulties attending present-day manufacture.—We are, etc.,

THE EDISON SWAN ELECTRIC CO. LTD.,
RADIO DIVISION.

*** We have referred this letter to the authors, and print below the reply from Mr. A. MacPhail.

SIR,—Reference is made to the paper by Fleming, Golla, and Grey Walter in the *Lancet* (1939, **2**, 1353). They describe how the patient is switched over to low-tension circuit, and voltage is adjusted until 1 mA flows through the head. From this the resistance is calculated. Because of the considerable discomfort caused by the passage of 1 mA of alternating current trans-temporally, and since the nature of the current was not mentioned, it was assumed that the direct current was used, as it is much more tolerable when gradually increased to this magnitude than the alternating current, and, indeed, we did not see why an already difficult patient should be subjected to electro-sensory changes for the mere measurement of resistance, especially when the current can be easily kept below the threshold of sensibility for measuring purposes. In our instrument this is done, and the patient at no time feels any electric sensations whatever, as Fleming, Golla, and Grey Walter admit their patients have.

We beg to tender our apologies for the statement that Mr. Grey Walter uses direct current for measurement of the trans-

temporal resistance, but when the nature of the current was not mentioned we believed that our inference was fair, knowing the discomfort of 1 mA of alternating current through the brain.

Our equipment is being manufactured by Electro-medical Engineers to our specification and is contained in a small attaché case at a cost of £40 complete.—I am, etc.,

Jan. 13. ANGUS MACPHAIL.

Oxygen Therapy

SIR,—In their valuable letter (January 18, p. 98) Mr. S. M. Cohen and Dr. W. W. Mushin have aptly drawn attention to the difficulties attending oxygen administration. This valuable therapeutic agent was used by Beddoes as far back as 1800, and in 1865 an oxygen administration apparatus was actually patented by Geo. Barth, who used it widely with apparent success.

Considering the paramount importance of oxygen in physiology, pathology, and therapeutics it is surprising that its use has been so long neglected. For is not oxidation the fundamental basis of all organic physiology, and diminished oxidation the basis of all organic pathology? Rationally, therefore, increased oxidation should be the primary aim of therapeutics. While agreeing with the writers of the letter as to the apprehension of patients and relatives being often an objection to its use, I would suggest two other considerations which also make the treatment unpopular—namely (1) the heavy and cumbersome apparatus, and (2) the cost. Neither of these difficulties need be encountered to-day, for a new type of short cylinder with a flat base, enamelled black with chromium-plated tap-fitting containing 100 cu. ft., not too heavy and fitting readily into most doctors' cars, can now be obtained.

With regard to cost, I think it is time that oxygen was controlled and made available to all doctors at a reasonable price—certainly not more than that charged to garages, oxy-acetylene welders, etc. At present I am obtaining oxygen in the cylinders described above from a firm which delivers it from a distance of thirty-five miles at an inclusive total cost of 3s. 9d. per cylinder, or £1 17s. 6d. per 1,000 cu. ft. Another firm only seven miles distant offered to supply similar cylinders at 9s. 6d. per cylinder—that is, £4 15s. per 1,000 cu. ft. As 100 cu. ft. of oxygen usually lasts about twenty-four hours it will be agreed that a cost of 3s. 9d. per day is within the means of almost anyone.

For several years I have administered oxygen in general practice by means of a small oxygen tent, which I think is preferable to the inhalation mask, especially in children. Treatment is begun in the early stages of illness, usually when the patient is obviously not in danger, and no anxiety is caused to either the patient or the relatives. I have used it in cases of pneumonia, pulmonary collapse, embolism and oedema, bronchitis, asthma, cardiac failure, whooping-cough, diphtheria, intestinal distension, narcotic and carbon monoxide poisoning, in children and adults, in all types of homes, usually with striking effect. Oxygen is a life-saver.

I hope that the Medical Planning Commission will arrange for the proper distribution of oxygen at a proper price. If it does, the profession and the public will soon be convinced of the extraordinary value of this simple remedy.—I am, etc.,

Liverpool, Jan. 20. ARTHUR G. C. FFOLLIOTT.

Adie's Syndrome

SIR,—The letter of Mr. R. Foster Moore (January 18, p. 99) claiming to have described this condition six or seven years before Adie illustrates the grave danger of eponyms. There can be no doubt that Mr. Foster Moore's communication (*Trans. ophthal. Soc. U.K.*, 1924, **44**, 38) has never received the recognition which it has deserved, probably due to the specialized nature of the journal.

But the pupillary condition was described by Ware in 1813, and later, in 1902, by Strasburger and also by Saenger. Its association with alteration of deep reflexes was recorded by Markus in 1905 and Gehrcke in 1921. All these authors can therefore claim priority over Mr. Foster Moore. Probably further probing into the literature would establish the fact that the condition was described even before 1800. I recall the aphorism of Kingston-Fowler, "To be original it is necessary not to read too much." I wonder if this haggling over priority would occur if Sir Jonathan Hutchinson's suggestion—that conditions be named after the patients in whom they were first seen—were followed.—I am, etc.,

Mitcham, Surrey, Jan. 21. MAURICE H. PAPPWORTH.

Medico-Legal

PRACTICE IN INSANITY DIVORCE SUITS

A petition for divorce on the ground that the respondent has been under care and control as a person of unsound mind for the five years immediately preceding the petition must necessarily be supported by medical evidence. Medical superintendents of mental hospitals are busy and responsible people, and attendance as witnesses in divorce actions throws an appreciable burden upon them. At the instance of the Official Solicitor, who usually acts as the guardian *ad litem* of the patient, the President of the Divorce Division recently instituted a practice whereby medical superintendents may in certain circumstances be allowed to give their evidence as to the state of mind of the patient by affidavit.[1] The procedure should, the President said, be used only where the medical superintendent can express, with reasons, an unqualified belief in the incurable unsoundness of mind of the respondent, and in the continuance of the care and treatment during the whole of the five years immediately before the petition. The affidavit also gives the medical superintendent an opportunity to deal in appropriate cases with other relevant matters, such as the provision of extra comforts for the patient. The superintendent's belief in the incurability of the patient must be unqualified. The President remarked that the words "It is my belief that the respondent is unlikely to recover" do not express such an absolute belief. Unlikelihood or improbability of recovery may be a very different thing from incurability. The new procedure is only apt when a medical superintendent feels himself able to express reasons for saying that the patient cannot be cured.

A SUCCESSFUL SILICOSIS APPEAL

It seems hard that the interpretation of a single word in a statute should make a vital difference to the life of a poor family. In deciding a recent appeal[2] the House of Lords were able to reconcile precision, common sense, and humanity. The compensation of workmen disabled by silicosis is dealt with by the Various Industries (Silicosis) Scheme, 1931. Compensation under this scheme may be paid only to workmen employed in a list of specified processes, one of which is the "crushing or grinding of silica rock, or any handling incidental to such crushing or grinding, or crushing or grinding of bricks or other articles containing not less than 80% total silica." A workman had to reline a furnace, and before doing so had to break down the old layers of silica brick. These, being cemented hard, required the use of crowbars, and the new bricks often had to be chipped into shape. Both processes generated large quantities of silica dust inside the cavity. The workman contracted silicosis from inhaling this dust and applied for compensation. The county court judge concluded that the workman was employed in "crushing" the bricks; but the Court of Appeal disagreed, largely on the ground that in other parts of the scheme "breaking" is mentioned as well as "crushing or grinding," and therefore seems to be regarded as a distinct process. Viscount Simon, however, on appeal to the House of Lords, agreed with the county court judge that the work inside the furnace could properly be called "crushing" the brick. The applicant had not only to cut the brick down by crowbar and mallet, but also to break down the old lining with sledge-hammers. This, he thought, comes within the dictionary definition "to compress with violence so as to destroy natural shape or condition: to comminute." His Lordship added that it must not be assumed that the application of one word in a scheme always excludes the possibility that another word may be applied to the same operation.

[1] *Times*, November 29, 1940.
[2] Forster *v.* Llanelly Steel Co. (1907), Ltd., 1941, 1 All E.R. 1.

Some crushing may justly be called breaking, and some breaking may amount to crushing. The other learned Lords agreed, and Lord Wright said that breaking and crushing both mean disintegration, and the difference is one of degree. In questions of the line between the application of one word and that of another the functions of the judge are peculiarly important. The judge's application of the word "crushing" to the facts could not be called insensible or such as a reasonable man could not make. The judge's order for compensation was therefore restored.

Universities and Colleges

UNIVERSITY OF OXFORD

The following medical degrees have been conferred in Convocation:

D.M.—Alice J. M. T. Barnes.

B.M.—E. Emanuel, C. M. Bisset, J. B. Searle, M. G. C. Ashby, B. S. B. Wood, P. E. Coffey, J. P. Rochford, E. J. S. Barthorpe, A. M. Joekes, G. E. Milne, P. A. L. Roberts, R. H. Gaman, *E. E. T. Taylor, *G. P. Mahar-Loughnan, *S. F. M. Cressall.

* In absence.

UNIVERSITY OF CAMBRIDGE

At a Congregation held on January 25 the appointment of Dr. T. S. Hele, F.R.C.P., Master of Emmanuel College, as deputy for the Professor of Biochemistry was continued to the end of the present academical year.

The following medical and surgical degrees were conferred:

BACHELORS OF MEDICINE AND SURGERY.—(By proxy.) J. S. Hesketh, M. R. Pollock, F. T. G. Prunty, M. A. Fawkes, O. Clarke, D. MacG Jackson, L. Read, P. F. Milling, R. C. Tufton, D. W. M. James, R. Morton, C. S. N. Swan, W. R. Burkitt, W. McC. Scott, J. O. D. Williams, A. G. Farr, L. A. Little, H. D. L. Campion, F. J. Y. Wood.

UNIVERSITY OF ST. ANDREWS

At a graduation ceremony held last month the following medical degrees were conferred:

M.B., CH.B.—R. B. Davidson. J. MacP. Jolly, Muriel Mackenzie, Christine N. R. Stalker.

SOCIETY OF APOTHECARIES OF LONDON

The Gillson Scholarship in Pathology of the Society of Apothecaries of London has been awarded to Dr. Helen M. Wright for the year 1941.

ROYAL COLLEGE OF OBSTETRICIANS AND GYNAECOLOGISTS

A quarterly meeting of the Council was held at the College House on January 25, with the Vice-President, Mr. Eardley Holland, in the chair.

Membership

The following were elected to the Membership:

Alice Josephine Mary Taylor Barnes (London), Arthur Patrick Barry (Dublin), Donald Rose Beaton (R.A.M.C.), Stanley Arthur Bond (London), Margaret Muriel Burton (London), Archibald Sutherland Duncan (Edinburgh), Howard Roderick Duval (London), Jack Joseph (London), Hugh Cameron McLaren (Aberdeen), John Clifford Newbold (London), Richard Braithwaite Keevil Rickford (London), Kenneth Garratt Seager (Croydon), Kantilal Chandulal Shah (Bombay), David Chalmers Wiseman (Leicester).

Malcolm Thomas Drummond (Sydney) was admitted to the Membership *in absentia*.

The President, Prof. W. Fletcher Shaw, was reappointed to represent the College on the Central Medical War Committee, and Mr. J. P. Hedley was renominated representative of the College on the Council of the Queen's Institute of District Nursing.

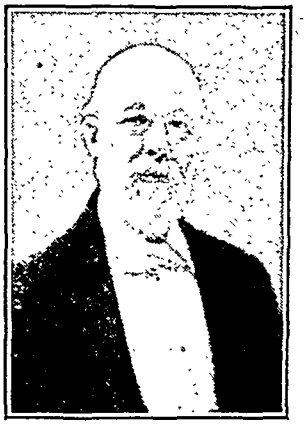
CONJOINT BOARD IN SCOTLAND

The following candidates, having passed the requisite examinations, have been admitted L.R.C.P.Ed., L.R.C.S.Ed., L.R.F.P. & S.Glas.:

M. A. Attia, R. R. B. Baxendine, M. Berman, R. H. Brundage, D. Collins, M. M. Dinowitz, M. Dirdack, M. L. A. El Diwany, S. C. J. Falkman, S. Finkelstein, Eleanor Franks, H. H. Frumin, F. Glass, A. A. Goldstein, G. Kilgour, I. Krauthamer, T. Lyle, D. MacKay, W. L. Milligan, Z. F. Nakhoda, R. M. Norwell, K. I. Peckitt, B. Schneider, W. Schreiber, H. J. J. Schwartz, M. Serlon, J. Simpson, F. Stein, R. Stewart, W. J. Taylor, H. B. Wender, T. Yong-Leng, A. H. Zidan.

The following graduates of recognized foreign universities were also admitted Licentiates:

E. Cohnreich, G. David, S. Geliebter, H. E. Haas, B. Hermann, E. Iscenco.



Obituary

FRANK T. PAUL, D.Sc., CH.M., F.R.C.S.

Consulting Surgeon to the Liverpool Royal Infirmary

Mr. F. T. Paul, the well-known Liverpool surgeon, died at his country home at Grayshott, Hindhead, on January 17, in his ninetieth year.

The son of Mr. Thomas Paul, he was born at Ashwood Lodge, Norfolk, and educated at the Yarmouth Grammar School. After a short time at a commercial office in London he entered Guy's Hospital, and qualified M.R.C.S. in 1873 and L.S.A. in 1874. After a year's residence as house-surgeon in Guy's he left London for Liverpool to spend the rest of his professional life in that city. His first appointment was that of resident medical officer at the old Royal Infirmary. This brought him into contact with the medical school—the nucleus of the University College and later on of the University of Liverpool. His extraordinary talents were soon recognized, and he rapidly scaled the whole range of appointments that Liverpool could offer him. Successively pathologist, lecturer in dental surgery, surgeon to the Southern and Stanley Hospitals, professor of medical jurisprudence, assistant and later full surgeon to the Royal Infirmary, he retired from the Infirmary in 1911 with the well-deserved reputation of being one of the leading surgeons of his day.

He had taken his Fellowship in 1878, and the University of Liverpool honoured him by bestowing upon him *honoris causa* the Mastership of Surgery and the Doctorate of Science. He was an enthusiastic supporter of the Liverpool Medical Institution, filling all its offices, and becoming its president in 1906 and 1907. He attained his jubilee of membership in 1925, and at the Centenary Meeting in 1937 he was elected an honorary member. Some years ago he gave to the Institution his presentation portrait and a model of his hand cast in bronze, a souvenir suggested by the original mind of the late Mr. Frank Jeans. On this interesting occasion Jeans spoke of the importance of delicacy of touch in a surgeon, whereupon Paul remarked that "a gentle touch comes from the heart rather than the hand—a touch inspired with a true sympathy for the patient's tissues."

Paul wrote little; a textbook on domestic economy and the article on intestinal obstruction in Binnie's *Surgery* were his chief publications. With a few exceptions—those in the *Transactions of the Pathological Society*—nearly all his papers were issued in the *Liverpool Medico-Chirurgical Journal*, and consequently did not reach the wide publicity among the profession that their contents merited. On the occasion of his seventy-fifth birthday his colleagues and friends collected all this material into a birthday volume of *Selected Papers*, which was published by Baillière, Tindall and Cox. This volume is of great interest, as it shows Paul's wide knowledge and originality. In it may be seen his first paper on colotomy in 1891, in which the use of Paul's tube is first mentioned, and the subsequent paper on colectomy in which he had perfected the method, often erroneously ascribed to Mikulicz,

who did not write of it until at least ten years later. In 1892 Paul wrote of his improvement on Senn's method of gastro-enterostomy by bone plates; substituting a bone ring for the bone plate and suggesting that the site should be the posterior and not the anterior wall of the stomach for the anastomosis. In 1894 he described an original method of amputation of the hip-joint, and as early as 1897 we find that he had done a partial thyroidectomy on six cases of exophthalmic goitre without a single death. In addition the book is full of microscopical studies of dentine, Nasmyth's membrane, chronic mastitis, and prostatic enlargement. Truly a remarkable achievement for one of that time.

As professor of medical jurisprudence he was often in court as an expert witness, and it is interesting to recall that he was called for the defence in the famous Maybrick case, when apparently the medical profession was as divided in its opinion as was the country generally. When the last war broke out, Paul as an *à la suite* officer was put in charge of the surgical division of the 2nd Western General Hospital at Fazackerley with the rank of major He did splendid work there as well as in the many subsidiary hospitals on both sides of the Mersey He had been a member of the British Medical Association for sixty-six years, and gave the Address in Surgery at the Liverpool Meeting in 1912.

Paul's surgical life spanned the change brought about by Lister. He often said that on his arrival in Liverpool the first surgeon he saw to wear suitable clothing for an operation was Edward Bickersteth, senior surgeon to the Royal Infirmary, who was a personal friend of Lister's. Paul early recognized the importance of the antiseptic system and the wide prospect it offered to the surgeon. He was a very hard worker, and soon found, to his surprise, that he alone was doing as many operations in a year as the whole staff of Guy's did in his house-surgeon days. His fame spread beyond the confines of Liverpool both as a brilliant surgeon and as an inspiring teacher. Modest and self-effacing to a degree, he was entirely without affectation, and was always ready to give a helping hand to his junior colleagues. It is difficult for anyone who saw Paul operate to speak of his work without superlatives. Moynihan himself said he was the neatest operator he had ever seen. When over 70 he performed delicate operations with a speed and dexterity which many younger men could not emulate.

He was very versatile, and in his younger days was a keen yachtsman, camper-out, and photographer. He was also an early motorist, doing his own running repairs. Gardening was perhaps nearest his heart, and he was something more than an amateur. In later years it remained his chief hobby and delight, and he grew orchids with great success at Grayshott. He expended on gardening the same skill and enthusiasm that he had given to surgery, bent always on the advancement of his craft.

Paul's name has already its allotted place in surgical history, but generations of students to whom he unfolded the fascination of surgery will remember him not only as a brilliant teacher but also as a kindly friend and wise counsellor. R. E. K.

[The portrait reproduced is from the presentation picture painted by G. Hall Neale.]

ERNEST W. LEWIS, M.D., F.R.C.S.ED.

We have to record with much regret the death on January 17 at Birkdale of Dr. Ernest William Lewis, honorary consulting surgeon to the Southport Infirmary and for many years an active worker in the British Medical Association. Dr. Lewis was born in South India on July 10, 1875, son of the Rev. Edwin Lewis, and from Keyford School, Frome, Somerset, went to Edinburgh University in 1892 to begin the study of medicine. He won distinction at the final M.B., Ch.B. examination in 1898 and commendation for his M.D. degree in 1906, and later obtained the F.R.C.S.Ed. Soon after graduation he held the post of house-surgeon at the Mildmay Hospital, Bethnal Green, and then returned to South India as surgeon in joint charge of the London Missionary Society's hospital at Jammalamadugu, a post he held for six and a half years. At Southport he became a member of the local bench of magistrates and served as mayor in 1933–4. Dr. Lewis joined the British Medical Association in 1900: he was honorary secretary of the Southport Division 1922–8 and chairman in 1929–30. He represented his Division at seven Annual Meetings and was president of the Lancashire and Cheshire Branch in 1934–5. At headquarters he had been a member of the Journal Committee since 1937 and also served on the Central Council during the same period. He was a member of the Liverpool Medical Institution and a Fellow of the North of England Obstetrical and Gynaecological Society.

A colleague, W. A. M., writes:

Graduating with distinction, Dr. Ernest W. Lewis spent some years in India, coming to Southport to engage very successfully in practice over thirty years ago. During the war of 1914–18 he worked at one of the local war hospitals. At this period his health broke down, and for some months he had to keep indoors after sundown. Undeterred, he prepared himself for and obtained the Fellowship of the Royal College of Surgeons of Edinburgh in 1918. Soon after he joined the staff of the Southport Infirmary, doing good work and interesting himself in the building of a new out-patient department, which had become necessary. When he retired on reaching the age limit he was chairman of the medical board. During this time he had filled the office of mayor of the town and been chairman of the local Branch of the B.M.A. In the present emergency he was vice-chairman of the Local Medical War Committee, joined the medical service, and as long as strength permitted worked as surgeon to the Southport War Emergency Hospital. When he recognized the inevitable, as unfortunately he had to some months back, he told his friends of his illness and carried on. Devoted to his family and his profession, he found time and energy for his municipal work, his flowers, and photography, but in the later part of his medical life his interest in and devotion to the work of the B.M.A. seemed to his friends the "ruling passion." When I called on him a few days before death and when anodynes at frequent intervals were necessary, Lewis wanted my opinion of the "Medical Parliament." So he leaves us with the memory of a calm courage all must admire and many of us envy.

J. R. KAYE, M.B., D.P.H.

Dr. James Robert Kaye, who served as county medical officer of health for the West Riding of Yorkshire for thirty-three years, has died at his home in Hove, Sussex, aged 85. A native of Perthshire, he received his medical education at the University of Glasgow, graduating M.B., C.M. in 1880, and taking the D.P.H. of Cambridge nine years later. While still an undergraduate his attention was drawn to the importance of hygiene by an outbreak of diphtheria, and he decided to devote his life to this branch of medical service. He was appointed M.O.H. for the West Riding in 1896: he reorganized the sanitary administration, and some twenty-five years ago had an important survey made of housing and sanitary conditions in the area under his supervision. He took an active interest in all sides of public health work, and arranged every year a "health week" for the West Riding. At the international congress of the Royal Institute of Public Health at Ghent in 1927 Dr. Kaye received the triennial award for conspicuous work in the cause of public health. He retired from his post in 1929: during his tenure of it the infantile death rate in the West Riding fell from 165 per

thousand to less than 80. In retirement on the Sussex coast he became honorary secretary of the Brighton, Hove, and Worthing Branch of the National Society for the Prevention of Cruelty to Children. He had joined the British Medical Association in 1893, and served as vice-president of the Section of Public Medicine and Industrial Diseases at the Bradford Annual Meeting in 1924. He had been president of the Yorkshire Branch of the Society of Medical Officers of Health, and during the last war held the rank of lieutenant-colonel R.A.M.C.(T.) as D.A.D.M.S. of the 2nd West Riding Division.

PROF. MAX ASKANAZY

In a recent issue of the *British Medical Journal* (writes Dr. Lina Potter) the death of two veteran professors of Geneva University was recorded: Prof. Cristiani of the Public Health Section and Prof. Max Askanazy of the Pathological Institute. Prof. Askanazy attracted many foreign students to his classes, and others in England besides the writer must have profited by his teaching. As a research worker he published work on the experimental propagation of cancer and on a wide number of other subjects. He was safe rather than daring, and when he published new work it was well documented and represented an enormous amount of investigation. He was the collaborator of Aschoff and was responsible for a section of his book. In July, 1939, a few weeks before the outbreak of war, he had just resigned his professorship at the age of 73 and was looking forward to attending a conference in the U.S.A. and to "a quiet time" of retirement to investigate a hundred and one subjects which had attracted his attention but had been put aside for routine work. His place as writer, teacher, and researcher, above all as an indefatigable worker in pathology, will be difficult to fill.

Dr. BENJAMIN MORGAN LEWIS, formerly of Sunnyside, Pontypridd, Glamorgan, died on September 28, 1940, at Bath. Son of Benjamin Lewis, Glanbarden, Govilon, Abergavenny, he was educated at Bath College and University College and Hospital, London. After qualifying M.R.C.S., L.R.C.P. in 1888, he at once went to Pontypridd and practised there for nearly fifty years. Dr. Lewis was one of the founders of the Pontypridd and District Hospital. An active member of the British Medical Association, which he joined in 1890, he was also a member of the Glamorgan Insurance Committee and Glamorgan Panel Committee. He married Marian, daughter of the Rev. David Wassell of Bath, who survives him with four sons and one daughter. "R. M. H." writes: I should like to pay tribute to this really great general practitioner. He is one of the many "Unknown Soldiers" who form the backbone of the medical profession. His passing removes one of the grandest type of general practitioners. He was indeed guide, counsellor, and friend to all his patients. He was held in the highest esteem by the members of his profession and on more than one occasion was urged to be a president of the Branch, but he shrank from publicity and preferred to carry on his good work in the background. His loss is deeply mourned by his colleagues and patients.

We regret to record the death on January 4, at the age of 77, of Dr. JOSEPH STEWART of Leeds. Dr. Stewart was born at Castlederg, Co. Tyrone, and was educated at Queen's College, Galway, and the Royal University of Ireland, where he took the degrees of M.B. and M.Ch., both with honours, in 1887. He had held the post of demonstrator in anatomy at Queen's College, Galway, and in 1889–90 he won a travelling scholarship, visiting London, Paris, Vienna, and Berlin. On his return he went into partnership with the late Dr. Robinson of Leeds, and soon afterwards married Miss Elizabeth Ann Miller of Galway, who died some years ago. Of his three sons only Dr. Barry Stewart, also of Leeds, survives him, one son being killed in the war of 1914–18 and another, Dr. Joseph Douglas Miller Stewart, who was in partnership with his father, died just over a year ago. Dr. Stewart had been a member of the British Medical Association for forty-nine years.

Dr. HENRY EDWARD SKYRME, whose death at Bournemouth occurred on January 12, was for many years a prominent and highly regarded practitioner in Cardiff. In his youth he was a chemist, but he forsook this for medicine and proceeded to the London Hospital, where he had a distinguished career, taking several medals and scholarships. Qualifying in 1888 with the Conjoint diplomas he then became a house-physician in the London Hospital, and not long afterwards settled in Cardiff. His success in practice was immediate and he soon built up one of the largest and best practices in the city, which he maintained until he retired to Bournemouth in 1922. He was a member of the British Medical Association for thirty-two years, and took an active part in the proceedings of the Cardiff Division, especially in the hectic Insurance Bill controversy of 1911; he was also a member and a former president of the Cardiff Medical Society. "G. I. S." writes: Dr. Skyrme led an active and a full life, and he was a most amiable man and a cheerful companion. He was an enthusiast in the early days of motoring, and possessed one of the first motor-cars in Cardiff. His wife died a year or two ago, and he is survived by an only daughter, who is married. Dr. Skyrme was one of the "old school," and the news of his death comes as a wistful reminder to those of us who are old enough to have known them and to have worked with them that the members of that esteemed generation are dropping off one by one.

Dr. DAVID RENNET, who died at Upton, Chester, on January 13, was the son of the late Mr. David Rennet of Aberdeen. Dr. Rennet was educated at the Aberdeen Grammar School and Aberdeen University, where he graduated M.B., C.M. in 1889, subsequently obtaining the D.P.H. at the same university. He received the degree of M.D. with commendation in 1893. Following a few years' general practice he became Assistant M.O.H. for Aberdeen City. He also was assistant professor of medical jurisprudence and public health in the University of Aberdeen, having been appointed in 1892. In 1911 he succeeded Dr. J. R. Currie (now Prof. Currie) as Medical Officer of Health for the city of Chester. Having been in the R.A.M.C. since 1907, Dr. Rennet was called up for service on the outbreak of the last war in 1914. He became specialist sanitary officer to the Western Command and was demobilized with the rank of brevet lieutenant-colonel in 1919. He subsequently received the M.B.E. During the tenure of his appointment in Chester many improvements in the public health were initiated by him, and he had the full confidence of the City Council. When he retired in 1932 he received presentations from past and present members of the City Council and members of the medical profession in the city, besides a presentation from the staff of the Public Health Department. He was a past-president of the Chester Caledonian Association, of which he was a member for many years. His wife died in 1936 and he is survived by two daughters, one of whom is a member of the medical profession. His loss will be keenly felt by many members of the medical profession and in particular by those who were fortunate to work under him in the Public Health Department in Chester. He was a member of the British Medical Association for twenty-one years.

Dr. GEORGE JAMES WILLIAMS, formerly of Haltwhistle, Northumberland, died suddenly on January 16 at Peterstone-super-Ely, Glamorgan. He was born at the beginning of 1865, and from University College, Aberystwyth, went to Newcastle-on-Tyne College of Medicine to study for the medical degrees of Durham University. He graduated M.B., B.S. in 1892 and proceeded M.D. in 1905. Dr. Williams was for a time surgeon to the G.W.R. at Fishguard, and Rosslare harbours and railways. He held a number of medical appointments at Haltwhistle, and during the last war was civilian medical officer to a brigade of the R.F.A. at Featherstone Park Camp. After moving to South Wales he became medical officer to the St. Fagans district of Glamorgan. He had been a member of the British Medical Association since 1894.

We regret to announce the death of Dr. HUGH BRINDLEY OWEN, D.S.O., which took place on January 17 at Penzance, where he practised as an ophthalmologist after a long period in the Uganda Medical Service as ophthalmic specialist and as

medical superintendent and principal of the Medical School of Mulago Hospital. He was born in 1879 and began the study of medicine at Caius College, Cambridge, which he entered in 1897, and afterwards at St. Bartholomew's Hospital, graduating B.Ch. in 1906 and M.B. in 1907. In the following year he took the D.T.M. and H. and went out to Uganda, and served with much distinction in the last war, being awarded the D.S.O. and the O.B.E. He took the D.O.M.S. of the English Royal Colleges in 1926, and after settling in practice at Penzance was elected ophthalmic surgeon to the West Cornwall Hospital in that town and to the West Cornwall Miners' and Women's Hospital at Redruth. He joined the British Medical Association in 1913 and served as Representative of the Cornwall Division at the Centenary Meeting in London in 1932. "Roddy" Owen, the name by which he was known to his many friends, was a prominent Rugby football player at Cambridge and at Bart's, for which he played as centre three-quarter in many inter-hospital matches at the beginning of this century.

Dr. JOHN FLETCHER HORNE was born at Barnsley, Yorkshire, in 1848, and received his medical education at Leeds and Edinburgh, qualifying in 1874, and later obtaining the F.R.C.S.Ed. At the time of his death he was the senior Fellow of that College. After serving an assistantship with Dr. James Braithwaite of Leeds, he acted as house-physician to Sir Clifford Allbutt at the General Infirmary, Leeds. He began practice in Barnsley in 1876, retiring in 1926. During his period in general practice he obtained the M.D. of St. Andrews University, and in 1896 was elected a Fellow of the Royal Society of Edinburgh. In 1894 he published a small volume on trephining, its ancient and modern aspects. From 1880 to 1900 Dr. Horne served on the surgical staff of the Beckett Hospital, Barnsley, and on retirement was appointed consulting surgeon. He was a member of the Barnsley Town Council for thirty-three years, and was mayor of that borough in the years 1900 and 1901. He was a Justice of the Peace for the Borough of Barnsley, and also for the West Riding of Yorkshire. He was a medical referee under the Workmen's Compensation Act, 1897, for thirty-two years. He had been a member of the British Medical Association for sixty-five years.

Dr. J. B. Horgan writes from Cork: The personality of HERBERT TILLEY has so permeated British rhinolaryngology for nearly two generations that only time can reveal the profundity of his loss. While never a pioneer Tilley early assumed a dominating position in his specialty and was always ready to bring an unbiased erudite and extremely ripe judgment to bear upon any question pertaining to his art. It was a natural sequence that his colleagues of all ages and in many lands learned to respect and indeed to rely upon the opinion of this courteous English gentleman. Tilley was always *au courant* with the cavalcade of progress which has attended the modern practice of surgery and medicine and applied this knowledge to his teaching and his practice. To quote his own simile, it is not enough for the labourer to till his own furrow, but he needs must cast his eyes upon the surrounding land and take note of the cultivation being carried out by his neighbours. The man has gone, but the gold of his endeavour will long remain as an inspiration to all those who were privileged to know him as a teacher or a friend.

We regret to announce the death of Dr. GEORGE WILLIAM HARVEY BIRD of Bridgwater, who was not only in private practice there but also held a number of public appointments, including that of medical officer of health. Dr. Bird, who was the son of a Kidderminster solicitor, received his early education at King's School, Worcester, and his medical education at Cambridge and St. Thomas's Hospital, qualifying M.B., B.Ch., and also M.R.C.S., L.R.C.P. in 1893. For a time he was house-physician and clinical assistant in the skin department at St. Thomas's, but in 1898 he went to Bridgwater as assistant to Dr. W. L. Winterbotham. Shortly afterwards they became partners, and when Dr. Winterbotham died Dr. Bird continued the practice himself. In 1923 Dr. Bird was appointed medical officer of health and school medical officer for the borough. Other official posts he held were those of medical officer of health to the Port Sanitary Authority, medical officer to the Post Office, and surgeon to the borough police force. He was appointed a member of the honorary medical staff of the Bridgwater Hospital in 1900, and at the time of his death was the senior member; he was keenly interested in the work of the hospital. With all his public work he found time for many other activities; he was a member of the Local Medical War Committee, chairman of the council of the Bridgwater Hospital League, while the work of the St. John Ambulance Brigade and the A.R.P. services also claimed his time and interest. He had been a member of the British Medical Association for forty-four years, and was chairman of the West Somerset Division in 1933–4. An appreciation of his services to the borough was given by the chairman of the education committee at a recent meeting: "Most of us came to regard Dr. Bird as something of an institution. He took great interest in every matter of importance in the town. He had very broad sympathies and wide interests. Not only will he be missed as a medical officer of health and by the education authority, but the town generally will miss him. It is the passing of a great gentleman and an accomplished medical man."

The death of Dr. JAMES BELL at the early age of 42 is severely felt by Trinity College, Dublin, of which he was a Fellow and lecturer in biophysics. He graduated M.B., B.Ch., and B.A.O. in the University of Dublin in 1934, afterwards taking the M.A., the Sc.D., and the M.D. degrees. Dr. Bell was a Fellow of the Institute of Chemistry and of the Chemical Society, to whose journal he contributed papers on the preparation and hydrolysis of guanidine and on the preparation of methyl and dimethyl guanidine. He had been a member of the British Medical Association since 1935.

The Services

HONORARY SURGEON TO THE KING

Colonel H. Stott, O.B.E., I.M.S., has been appointed Honorary Surgeon to the King, vice Colonel F. F. S. Smith, I.M.S., retired.

AWARDS

MENTIONS IN DISPATCHES

Surgeon Lieut.-Commander Kirk Forsythe, R.N.V.R. (H.M.S. *Cairo*), has been mentioned in dispatches for courage and endurance in action against enemy aircraft in Norwegian waters.

Corrigenda

In the list of officers whose names have been brought to notice in recognition of distinguished services in connexion with operations in the field, March to June, 1940, published in the *Journal* of January 4, the following were omitted: *Commands and Staff:* Colonels T. S. Blackwell, A. L. Foster, R. K. Mallam, O.B.E., M.C., and F. R. B. Skrimshire.

In the list of officers whose names have been brought to notice in recognition of distinguished services in connexion with operations in Norway, published in the *Journal* of January 4, the name of Colonel J. E. Rusby, M.C. (Commands and Staff) was omitted.

In the list of officers mentioned in dispatches, published in the *Journal* of January 4, the name of Colonel A. C. Searle should read Colonel A. C. Hammond Searle and that of Major A. E. King should be Major A. C. King.

CASUALTIES IN THE MEDICAL SERVICES

ROYAL NAVY

Surgeon Lieut. THOMAS JAMES MORTON, R.N.V.R., lost his life at sea in January. He was the only son of Dr. J. L. Morton of Colyford, East Devon, and received his medical education at Charing Cross Hospital, qualifying M.R.C.S., L.R.C.P. in 1936 and taking the degree of B.Ch. of the University of Cambridge in the same year. He had held the posts of house-physician, house-surgeon, and casualty officer at Charing Cross Hospital, and at the outbreak of the war was medical officer to the Hull and Sculcoates Dispensary. He joined the British Medical Association in 1938.

ROYAL ARMY MEDICAL CORPS

Wounded

Captain Douglas Blyth Milne.
Captain (War Substantive) Arthur Lloyd Potter.

Medical News

The Right Hon. Walter Elliot, M.P., F.R.C.P., formerly Minister of Health, has been appointed Director of Public Relations at the War Office in succession to Major-General J. H. Beith.

A meeting of the Shaftesbury Military Hospital Medical Society will be held at the hospital on Tuesday, February 4, at 3 p.m., when Major Barbour will speak on "Morale in Time of War."

A meeting of the Society of Public Analysts and Other Analytical Chemists will be held at 2.30 p.m. on Wednesday, February 5, at the Chemical Society's Rooms, Burlington House, Piccadilly, London, W.

The Chadwick Trustees recently offered two prizes of £100 and £50 for essays on the construction and management of air-raid shelters, with special reference to ventilation, heating, sanitation, and the provision of sleeping accommodation. They have awarded the first prize for the essay submitted jointly by Phillip O. Reece, A.M.Inst.C.E., and S. L. Wright, M.D., M.R.C.P., D.P.H., of Wembley, and the second prize to Jocelyn F. Adburgham, L.R.I.B.A.

The British War Relief Society in New York has promised to contribute to St. Dunstan's £5,000 a month for the next five months, and has also made a gift of £5,000 to the British Hospitals Association to increase and ensure the supply of radon.

In a message of appreciation to local authorities the Minister of Health, Mr. Malcolm MacDonald, said that owing to the need for giving little publicity to air-raid damage the public had not fully grasped the capable way in which local authorities had shouldered the heavy burdens thrust upon them. Local authorities had borne much of the brunt of the battle for Great Britain. The rescue of people from damaged buildings, the care and treatment of the injured, the repair of houses and of water and sewage mains, and the rehousing of the homeless were only a few of the tasks that had fallen on them and their voluntary and regional helpers. Local authorities in reception areas had been called upon to deal with increases in population of anything between 50% and 70%, and had managed to do this cheerfully. There had been some shortcomings and some failures, but generally local authorities had risen to the occasion with resource and efficiency.

The names of Dr. Matilda Carson Welsh (Salford) and Dr. Thomas Philips Cole (Beckenham) have been brought to notice for brave conduct in civil defence.

Reports that it is not possible to get treatment at Droitwich are incorrect. Accommodation is, it is true, limited, and should therefore be engaged well in advance. The St. Andrew's Brine Baths are open, and so are the rheumatism hospitals and hostel. Information can be had from the local Spa Association.

Medical Notes in Parliament

Administrative Duties of R.A.M.C. Officers

Captain MARGESSON, in reply on January 22 to Dr. Morgan, said many officers of the R.A.M.C. were engaged exclusively on administrative work which could not be efficiently performed by laymen. He was not aware of any disquiet among medical practitioners in consequence. Certain appointments were being reviewed which had in the past been held by medical men but could, with an adjustment of duties, be held by non-medical men. Some medical officers had already been replaced.

Fortified Bread

Answering questions on January 22 by Sir Ernest Graham-Little and Mr. De la Bere, Mr. HARCOURT JOHNSTONE, on behalf of the Ministry of Food, said the cost of fortifying white flour with vitamin B_1 was not expected to exceed one-tenth of a penny per quartern white loaf. The Government had not undertaken the manufacture of this vitamin. It would for the present obtain supplies from a firm of chemical manufacturers. Proposals by two other firms had been considered. In a reply to Mr. Stokes on January 23 Mr. Johnstone said wholemeal bread made from 100% extraction flour contained per ounce about 28 units of vitamin B_1, but bread made from such a flour was not fully digested. Bread made from flour of 85% extraction, which was to be the minimum for a wholemeal flour, would contain about 20 units per ounce of vitamin B_1. It was proposed to add that vitamin to white flour in sufficient quantity to raise the content also to 20 units per ounce.

Mr. JOHNSTONE told Mr. Thorne on January 23 that a report by Dr. I. Harris of Liverpool upon the use of calcium in bread had been examined. To add calcium to bread was the Government's announced policy. The method and the amount to be added were under consideration.

Influenza Prevalence

Replying to Sir Francis Fremantle on January 23, Mr. MACDONALD said there was no evidence at present of any general epidemic of influenza. In the 126 major cities and towns of England and Wales during the four weeks ending January 13, 1940, there were respectively 27, 45, 94, and 158 deaths from influenza. The comparable figures for 1940–1 were 30, 40, 53, and 74. It was impossible to estimate with any precision the incidence of the disease in the coming months. Experience suggested that, unless a sudden marked increase in the number of deaths from influenza occurred in the near future, a serious epidemic would not supervene. All practicable steps had been taken to deal with the more serious possibilities.

Recall of Army Doctors for Civil Needs

On January 28 Sir FRANCIS FREMANTLE asked the Secretary of State for War if he would consider the seconding of medical officers from the Army, with arrangements for their instant recall in case of need, to relieve the excessive demands made on medical practitioners by the calling up of younger men and by the greatly increased demand for medical attention to the civil population during the winter months. Captain MARGESSON replied that applications for the temporary release from the Army of medical officers to meet the needs of the civil population had been, and would continue to be, sympathetically considered, but it must be remembered that the Army could ill spare their services.

Dyspepsia in the Army

On January 28 Sir FRANCIS FREMANTLE asked the Secretary of State for War what percentage of cases invalided from the British Expeditionary Force to this country were suffering from gastro-duodenal disease, and whether strict instructions would be given to recruiting boards to reject men with a history of organic dyspepsia, and save the loss and inefficiency caused thereby to the Army. Captain MARGESSON said that the percentage of patients suffering from gastro-duodenal disease among hospital cases invalided from the British Expeditionary Force was 11.76. In reply to the second part of the question, strict instructions on the point had already been given to recruiting medical boards.

Specialists as Medical Referees

On January 28 Mr. PEAKE informed Mr. Robert Gibson that ophthalmologists had been appointed as medical referees under the Workmen's Compensation Act for the Sheriffdoms of Lanark, Lothians and Peebles, and Renfrew. Medical referees to deal specially with cases of scheduled diseases (including dermatitis) had been appointed for the Sheriffdoms of Lanark and Renfrew. The Home Secretary appreciated that it might be desirable to strengthen the panels of medical referees in these and other areas by more extensive appointments of specialists, and he would be very glad to consider representations in regard to any particular area. Experience showed that it was extremely difficult to secure the services of suitable specialists as referees under present conditions.

Repatriation of Medical Prisoners of War

Mr. SAVORY on January 28 asked the Secretary of State for War what steps were being taken to facilitate the repatriation of medical officers serving in His Majesty's Forces, and now

captives in Germany. Captain MARGESSON said that the German Government had been informed that His Majesty's Government was ready to repatriate the German medical personnel who were entitled to repatriation under the Geneva Convention of 1929, if the German Government would also conform to the terms of the Convention as regarded British medical personnel in their hands. The matter was being actively pursued, but a satisfactory settlement had not yet been reached.

Tuberculous Persons in Shelters.—On January 22 Mr MACDONALD stated that in addition to taking power to exclude a tuberculous person from a public shelter if his presence in the shelter was likely to be dangerous to other shelterers, he had made suggestions to local authorities for dealing with this problem. The responsibility for safeguarding the public health in any particular area rested in the first instance on the medical officer of health for the area. He had no doubt that officer would take steps to secure the provision of alternative shelter accommodation for any tuberculous persons for whom he thought such provision necessary in the public interest.

Notes in Brief

Mr. Lyttelton is reviewing the question of the restriction of 50% on the making of surgical belts and elastic hosiery for medical purposes.

EPIDEMIOLOGICAL NOTES

Infectious Diseases for the Week

The last week of 1940 is remarkable in that, with the one exception of cerebrospinal fever, the incidence of the important notifiable diseases has declined compared with the preceding week. It is probable that delays in getting the returns from outlying areas, and perhaps a tendency to postpone notification for a few days until holidays are over, have been factors in the observed decreases, and the figures for next week may show a corresponding artificial change in the opposite direction.

Notifications of cerebrospinal fever were the highest for twenty-three consecutive weeks, being nearly four times those for the last week of 1939. Although the number is small compared with the peak figure of 623 in the week ended March 2, 1940, the early rise must give cause for some anxiety on account of present conditions. The disease is present in over two-thirds of the sixty-one administrative areas of the country, all of them potential foci for outbreaks of epidemic magnitude. The areas most heavily involved were: Lancaster 14 (Liverpool 7, Manchester 2, Bootle, Burnley, Blackpool, Leigh M.B., and Kirkham U.D., 1 each); London 12 (Kensington 4, Camberwell 2, Battersea, Bermondsey, Fulham, Hammersmith, Lewisham, Poplar, 1 each); Warwick 11 (Birmingham 7, Coventry 2, Sutton Coldfield M.B. 2); Chester 10 (Chester 3, Birkenhead 2, Altrincham M.B. 2, Congleton M.B. and Chester R.D. 1 each, Runcorn R.D. 1); Glamorgan 7 (Cardiff 3, Llwchwr U.D. 2, Port Talbot M.B. and Pontypridd U.D. 1 each); Durham 6 (Darlington and Sunderland 1 each, Felling U.D. 2, Billingham U.D. and Lanchester R.D. 1 each); and 5 each in the following administrative areas: Derby, Gloucester, Northumberland, Salop, Sussex W., Worcester, Yorks, West Riding, and Monmouth.

Measles is by far the more prevalent infectious disease at present, and it is probable that the incidence will continue to rise during February and March, but the abnormal conditions forbid even tentative prophecies. In the winter and spring of 1939–40, when measles was expected in epidemic force in accordance with its usual biennial periodicity, incidence was abnormally low, except in two densely populated administrative areas—Lancaster and the West Riding of Yorks. Whooping-cough, the next in order of prevalence, has also risen in recent weeks. The case-fatality of whooping-cough is nearly always higher than that of measles and much more invalidity follows in its train.

In August and September the fall in incidence of measles is attributable in part to climatic factors and in part to the effects of evacuation on the distribution and exposure of the non-immunes. With the advent of winter the increase has been progressive but not uniformly so. The steady low level of whooping-cough furnishes a striking contrast.

No. 52 for 1940

INFECTIOUS DISEASES AND VITAL STATISTICS

We print below a summary of Infectious Diseases and Vital Statistics in the British Isles during the week ended December 28, 1940.

Figures of Principal Notifiable Diseases for the week and those for the corresponding week last year, for: (a) England and Wales (London included), (b) London (administrative county), (c) Scotland, (d) Eire, (e) Northern Ireland.

Figures of Births and Deaths, and of Deaths recorded under each infectious disease, are for: (a) The 126 great towns in England and Wales (including London), (b) London (administrative county), (c) The 16 principal towns in Scotland, (d) The 13 principal towns in Eire, (e) The 10 principal towns in Northern Ireland.

A dash — denotes no cases; a blank space denotes disease not notifiable or no return available.

Disease	1940 (a)	1940 (b)	1940 (c)	1940 (d)	1940 (e)	1939 (Corresponding Week) (a)	1939 (Corresponding Week) (b)	1939 (Corresponding Week) (c)	1939 (Corresponding Week) (d)	1939 (Corresponding Week) (e)

QUERIES AND ANSWERS

Diphtheria Incidence: A Small-pox Analogy

Dr. C. KILLICK MILLARD (Leicester) writes: Dr. Robert Anderson's reply (January 25, p. 144) to Dr. R. M. Courtauld is intended to demonstrate, presumably, the value of diphtheria immunization by comparing it with vaccination against small-pox. In both cases it has been established that those individuals who have been protected (vaccinated or immunized) show a far smaller incidence of small-pox or diphtheria than those who have not been protected. This has often been regarded as conclusive evidence of the value of vaccination or immunization in protecting the community. Indeed, the case for vaccination in the past was largely based upon it. Unfortunately there is a possible fallacy in this argument, for it is not safe to argue from the individual to the community. Personally I believe that the case for vaccination in protecting a community has been greatly overrated on account of this fallacy, and to-day most authorities will agree, I think, that small-pox has vanished from this country for quite other reasons than vaccination. In India, on the other hand, vaccination (although it protects the individual, as in this country) has signally failed to protect the community, and the death rate from small-pox in India continues to be appalling, although the amount of vaccination and revaccination done there is, in proportion to population, far greater than in this country. In the case of immunization against diphtheria, although it has been proved that it protects the individual, we are still awaiting conclusive evidence (from this country) that it will protect the community. How many (if any) towns or districts can we point to where there is evidence, as yet, that diphtheria mortality has been reduced as the result of immunization? I am certainly not opposed to immunization, and very much of my time at present is being devoted to the immunizing of children against diphtheria.

Dysmenorrhoea

Mr. A. J. HOBSON, F.R.C.S. (Wimbledon), writes: I should like to recommend the following prescription to "Country Practitioner" (December 28, p. 924) for use in dysmenorrhoea:

℞	Ac. lact.	gr. cc
	Cret. praecip...	gr. lxxv
	Chlorof.	ɱviij
	Aq. .. .. ad	ʒviij

F.m. Sig.: ʒj, t.d.s., p.c.

The mixture should not be made any stronger than this, and no more than four days' supply prepared at once, otherwise it becomes thick and valueless. I find that it cures or substantially relieves three out of four cases of dysmenorrhoea without organic cause. It is also an excellent curative and even better prophylactic for chilblains. It is, in fact, the only medium I have yet encountered by which calcium can be introduced to the human economy in a satisfactory way by the oral route.

Prevention of Herpes Labialis

"H. A." writes: I should be grateful for suggestions for the prevention of recurrent attacks of herpes labialis. The patient, a lady, never suffered from the attacks till four years ago, but now has attacks frequently; she attributes it to infection from another sufferer.

Treatment of Snoring

Dr. GEORGE MACDONALD (London, W.1) writes: I have been consulted recently by patients who snore. In view of so much communal sleeping this complaint has become of pressing importance. I wonder if there is any way in which I could find out the latest information about it with regard to a line of treatment. It struck me that possibly some ideas might have developed as a result of the present situation.

Income Tax

Cessation of Practice—Commencement of Appointment

"J. C." ceased general practice three years ago and afterwards accepted a public appointment. How should his earned income be calculated?

*** *Cessation.*—The income for the financial year in which the general work ceased should be calculated at the amount of the earnings for the period from the previous April 6 to the date of cessation; as regards the previous financial year the Revenue has the right of raising the assessment to the amount of the earnings for that (actual) year. If this was not done at the proper time the Revenue can now correct the omission by making additional assessments, but it is not seen why they should claim to do so "in respect of the last three years."

Commencement.—The rule is, as regards (*a*) the part of the first year to April 5—the actual basis; (*b*) the first complete financial year—the actual basis; and (*c*) the next year—the previous year's earnings—that is, the same amount as for (*b*). It should, however, be borne in mind that if the earnings for the third year—that is, (*c*) above—are less than the amount assessed, the taxpayer can claim, within twelve months, to have the assessment reduced to the actual basis. The standard rates of tax in recent years have been: 1939–40, 7s. in the £; 1940–1, 8s. 6d. in the £. The expense of "J. C.'s" postgraduate course is not regarded as allowable.

War Service—Civil Emoluments

"BELFAST" is in the Army, and his employers are making him an *ex gratia* payment to supplement his Army pay. Are these amounts liable to tax?

*** Yes. They are received in respect of his past civilian services, and cannot be successfully argued to be "gifts."

LETTERS, NOTES, ETC.

Definition of Surgical Shock

Mr. A. P. BERTWISTLE, F.R.C.S.Ed., writes: The need for clarification of the meaning of the word "shock" is obvious to all who teach first-aiders. The term "shock" has many meanings to the layman. I suggest that the adjective "surgical" would help to clear his mind of the other shocks he knows of. The actual nature of the underlying factors is still in dispute, but the theory which regards it as dilatation of the capillaries of the voluntary muscles fits in best with the findings and treatment. The following definition appears to be as good as any: *Surgical shock is a condition of depression or helplessness due to loss of circulating blood brought about by actual haemorrhage, pain, anxiety, or cold, or by all four factors acting together.* The best example of surgical shock is the patient who has just had a severe operation and has recovered from the anaesthetic. At least one member of the class will have seen such and can describe it to the rest in words intelligible to the layman. This definition suggests the treatment. Bleeding is arrested as soon as possible; fluids, and above all transfusion, make up this loss. Pain is relieved by gentle splints for fractures, and morphine at the post. Anxiety is relieved by efficient work by the team. Cold is countered by blankets and hot-water bottles.

Ether Convulsions

Dr. W. F. COOPER (Raynes Park, S.W.20) writes: The following point may be of interest and might possibly produce some solution of the difficulty. In working out the best saline for tissues much work has been done on most of the ions. But one which is always present in tissues, blood, etc., has had very little work done on it, is seldom considered in salines, and never used. That is the magnesium ion. This is a very peculiar ion, and so it is the more odd that so little has been done on it. Bayliss in *General Principles of Physiology* (1918) gives an account of it. On page 217 he refers to the work in which Meltzer showed that only about one-tenth of the amount of ether normally used was necessary if magnesium sulphate solution were injected intramuscularly. Some of us will have used it, probably to augment the effect of morphine in obstetrics—and it certainly seems to be good. So that it seems that the magnesium ion has some sedative effect, and this suggests that the convulsions may be due to lack of it in the blood of those particular patients; that the cure and also prophylactic measure would be to inject it. In fact, it seems extremely odd that this work has not been followed up as a possible routine method of anaesthesia. Some patients do seem to be lacking in magnesium in so far that it is often very beneficial. I believe that it is always good to give in any skin affection, and by injection sometimes; and this applies to eczema more than anything.

SUPPLEMENT TO THE
BRITISH MEDICAL JOURNAL
LONDON SATURDAY FEBRUARY 1 1941

Correspondence

The New War Damage Bill

SIR,—Dr. Henry Robinson (*Supplement*, January 25, p. 10) very properly reminds the medical profession that it is very deeply concerned with the provisions of the above Bill. As regards the voluntary part of the scheme—our private goods and chattels—he adds that it will be of interest to discover the reactions of the insurance companies on this matter. At the moment they are rather in the dark, but here is a personal experience gained only yesterday. The insurance company consulted strongly advises their clients to make an inventory *now* of everything in the house, and to deposit one copy with them. In the average household this can usually be done without seeking professional aid.

If the householder's ordinary peacetime fire policy only covers his goods and chattels for one-fourth of their value—say £500—and he now seeks war protection to the maximum of £1,500, he will find it difficult to convince the Government that he is not either under-insured or over-insured, with a consequent subsequent loss to himself. The company consulted therefore advised that both the peace and war policies should be for the same amounts. Under these conditions a war premium on, say, £1,000 will cost about £25 per annum, payable only for the duration, with any necessary readjustment in the peacetime premium. The reverse position is discussed by Dr. Robinson in his article.

With only partial destruction of goods and chattels from enemy action the insured person without an inventory may experience considerable difficulty in obtaining even an approximate compensation. The compilation of the inventory so strongly urged upon us is a staggering and illuminating commentary on what one stands to lose in the way of clothes alone. Try it and see, and do not forget your wife's fur coat.—I am, etc.,

Bristol, Jan. 25. RICHARD J. A. BERRY.

Medical Calling Up

SIR,—There appears to be a great deal of misgiving among members of the medical profession as to who should and who should not be called upon for service in the Forces, and, judging from the weekly list of casualties in the medical services published in the *British Medical Journal*, it is obvious that there is a growing demand for medical men for the Forces both at home and abroad. I would like to suggest that instead of expecting general practitioners to abandon their practices in order to join up the public health departments all over the country should be carefully scrutinized with a view to ascertaining how many medical men below the age of 45 can be spared from those departments for service in the Forces. These men can be more conveniently released from their civilian posts than general practitioners, as there are many of 45 years or less who are medical officers of health or assistants who, I think, will be anxious to join up if released by their councils, and who can be replaced for the "duration" by either assistants above the age of 45 having sufficient experience, or retired medical officers and assistants willing to do duty for a time to ease the situation.

Further, I would suggest that in calling upon medical men for compulsory service they be selected from those in the age groups 40 to 45 years or more first, leaving the lowest groups (usually those who are newly qualified) to be called up last, so that they will have an opportunity of gaining some experience before joining the Forces. This will also prevent those of the 40 to 45 age group from slipping into a category that may be considered too old for service.—I am, etc.,

Warrington, Jan. 22. C. A. PAULUSZ.

Bonus for Local Government Officers

SIR,—Although this does not affect me personally, I would like to take the opportunity of thanking the British Medical Association for persuading the present Minister of Health to reverse the rather extraordinary decision of his predecessor in this matter. You may be assured that the successful efforts of the Association will be widely appreciated by those concerned.—I am, etc.,

G. B. PAGE,
Exeter, Jan. 20. Medical Officer of Health.

DOCTORS MUTUAL ASSISTANCE SCHEME IN ACTON

Dr. H. L. Sparrow, chairman of the West Middlesex Division of the British Medical Association and of the Local Medical War Committee, has sent us the following details of a scheme providing assistance for doctors and their practices in the borough of Acton.

The object of the scheme is to afford professional assistance to any practitioner practising in or near the boundary of Acton in the event of his being killed by enemy action or incapacitated for the same reason, or his house or surgery being rendered uninhabitable. It is not the intention of this scheme to interfere in any way with the working of the Middlesex Protection of Practices Scheme: it is intended only to tide over the practitioner (or his executors) until his practice is disposed of or he has sufficiently recovered to resume work, or his house has been made usable or he has found other suitable premises.

It is suggested that Acton be divided into areas with an area officer in each, to whom the doctor or his representatives can immediately appeal for assistance. Each area officer will hold a list of six or seven practitioners who have expressed their willingness immediately to look after whole or part of the practice of a colleague. Work so done will be free, and any private patients attended by any acting doctor will be charged by him and the fee refunded at stated intervals to the practitioner for whom he is acting. If a doctor's premises are rendered unusable and the doctor himself is not injured, the area officer will, on application, arrange with a neighbouring practitioner for the temporary use of his surgery. It is suggested that such assistance would be granted for a period not exceeding one month, but this period could be extended with the approval of the committee.

DIPHTHERIA IMMUNIZATION

The text of a letter on this subject, which has been sent by the Secretary of the British Medical Association to Medical Officers of Health in England and Wales, was published in the *Supplement* of January 11, 1941. Section (*d*) of the Association's scale of fees is as follows:

> (*d*) These fees are inclusive of a report to the local authority. The report should be as simple as possible, providing for the name of the patient, the date of the inoculation(s), the amount and name of the reagent used, the identification number of the reagent, and the result of the immunization.

A medical officer of health has suggested that the form of report should include the address of the patient in addition to the other details mentioned. The address is an important means of identification, especially in county areas, where it enables the immunized persons to be more readily classified in their respective towns and villages.

DENTAL BOARD GRANTS

The Dental Board has been compelled by the reduction of its income consequent upon war conditions to discontinue the allocation hitherto made of large sums of money for dental research. The maximum which the Board found it possible to allocate for this purpose in 1940 was £250. In many instances research work, apart from any question of the Board's grants, has been suspended, but the Board has been anxious to provide, within the limited amount mentioned, for those cases in which dental research is still being pursued but might be closed down if the grant were not forthcoming. With this in view it has made a grant of £50 to the University of Birmingham in order that certain facilities in the dental research department may remain in being. The following grants by the Board in aid of teaching schools, on certain specified conditions, have been accepted: three grants at the rates of £500, £250, and £250 a year to the University of Birmingham towards the salaries of a professor of dental surgery, an assistant clinical instructor, and a demonstrator in dental pathology; two grants of £325 and £175 to the University of Liverpool towards the salaries of a demonstrator in conservative dental surgery and a demonstrator in orthodontics; two grants of £250 to the School of Dental Surgery of the Royal Dental Hospital of London in aid of the salary of demonstrators in the orthodontic and conservation departments; two grants of £500 and £250 to the University of Sheffield towards the salaries of a professor in dental surgery and a lecturer and demonstrator in dental mechanics, and a grant of £200 a year to the University of Leeds towards the salary of a demonstrator in prosthetic dentistry.

Medical Services of H.M. Forces

Appointments

ROYAL NAVY

Surgeon Lieut.-Commander D. F. Walsh to be Surgeon Commander.

ROYAL NAVAL VOLUNTEER RESERVE

Probationary Surgeon Lieuts D. Rice, C. A. J. Sampson, S. A. Swanson, and C. W. Levitt to be Surgeon Lieutenants.

Probationary Temporary Surgeon Lieuts. J. H. A. Jewell, H. T. L. Broadway, R. C. Bennett, J. H. Cobb, and A. J. G. Pullar to be Temporary Surgeon Lieutenants.

ARMY

Colonel J. T. Johnson, D.S.O., retired, late R.A.M.C., has reverted to the rank of Lieut.-Colonel at his own request whilst employed during the present emergency.

ROYAL AIR FORCE

Flight Lieut. T. C. Macdonald has been promoted to the war substantive rank of Squadron Leader.

Flight Lieut. N. Mackenzie has relinquished his short service commission on account of ill-health.

Flying Officers A. G. Burke and W. R. Parker to be Flight Lieutenants.

ROYAL AIR FORCE VOLUNTEER RESERVE

Flying Officers D. Wilson, D. St. C. L. Henderson, and B. B. Botha to be Flight Lieutenants.

Flying Officers A. N. H. Peach, B. A. E. Harley, J. North, D. W. Mahon, M. Hamilton, W. R. Mackie, J. G. Moloney, and J. Evans have been promoted to the war substantive rank of Flight Lieutenant.

J. P. Griffiths to be Flying Officer.

The notification in the *London Gazette* of December 20, 1940, concerning J. L. Trent and J. G. M. McMurchy should read Flying Officers and not Pilot Officers.

The notification in the *London Gazette* of December 31, 1940, concerning W. Poskett should read W. Foskett.

REGULAR ARMY RESERVE OF OFFICERS

ROYAL ARMY MEDICAL CORPS

Colonel E. M. O'Neill, D.S.O., has ceased to belong to the Reserve of Officers on account of ill-health.

TERRITORIAL ARMY

ROYAL ARMY MEDICAL CORPS

Supernumerary for Service with Glasgow University Contingent (Medical Unit) O.T.C.—E. W. Walls, late Cadet Lance-Corporal, Hillhead High School Contingent (Junior Division) O.T.C., to be Lieutenant.

TERRITORIAL ARMY RESERVE OF OFFICERS: ROYAL ARMY MEDICAL CORPS

Captain S. G. Reed has ceased to belong to the Territorial Army Reserve of Officers on account of ill-health.

LAND FORCES: EMERGENCY COMMISSIONS

ROYAL ARMY MEDICAL CORPS

The surname of Lieut. A. A. Alderdice is as now stated, and not as notified in the Supplement to the *London Gazette* dated July 19, 1940.

Lieut. H. Ferguson has relinquished his commission.

Dr. (Lieut.) Mrs. Mabel G. Bain has relinquished her appointment.

Lieut. B. G. Kelly has resigned his commission.

Lieut. J. Garden has relinquished his commission on account of ill-health.

To be Lieutenants: J. Brown, J. L. Macaulay, J. R. Dunn, H. Sington, P. H. Deeny, T. W. Sweetnam, F. E. Adams, T. R. Hill, N. Hockman, T. A. Kelly, D. W. Moynagh, W. F. Nicholson, M. A. Shellim, J. Kay, J. W. Dent, C. T. Gasking, F. Lanceley, J. M. Mair, J. H. Ramage, R. W. Panton, I. A. B. Cathie, L. G. Cook, R. J. V. Pulvertaft, H. S. Legge, G. D. McDowall, A. G. N. Calder, S. Chatterjee, J. W. Clark, A. I. Clay, B. R. M. Johnson, A. L. McLeod, H. J. Newlands, A. B. Linton, N. Rees, W. M. Shearer, R. M. Solomon, G. R. Taylor, D. C. Williams, J. D. Ballantine, T. H. C. Barclay, E. I. M. Catraher, K. W. Evans, I. S. Ede, E. G. Hardy, W. I. A. Heron, W. N. Hine, J. M. Knight, D. G. McReera, B. O. Moore, R. S. Patrick, J. Speer, J. A. Weir, J. A. Liley, B. Freedman, T. H. B. Fuller, B. A. Furniss, R. H. Isaac, Y. Premsukl, J. P. Jackson, L. E. D. Knights, G. Mann, R. K. Pillay, R. S. Risk, I. Seaal, R. S. Stevenson, P. S. Thorne, F. R. Turner, H. R. Anand, R. L. Coulter, L. H. Davies, G. Carter, W. N. Gilchrist, R. W. S. Harvey, W. G. Healy, W. Herbert, J. F. Heslop, J. G. Gillan, E. Joffe, J. S. Kerss, A. McLeod, W. W. Newman, J. M. Peden, A. N. Surtine, K. W. Todd, H. A. Tod, J. McD. Dougan, L. Redhouse, J. S. Barker, F. B. Youge, P. W. D.-Rowell.

B.M.A. LIBRARY

The following volumes were added to the Library during November, 1940.

Aris, N.: Parents and Children. 1940.
Bailey, H., editor: Surgery of Modern Warfare. Parts I and II. 1940.
Berman, J. K.: Synopsis of the Principles of Surgery. 1940.
Britton, H. T. S.: Chemistry, Life, and Civilization. 1940.
Brown, W.: Psychology and Psychotherapy. Fourth edition. 1938.
Conybeare, J. J., editor: Textbook of Medicine. Fifth edition. 1940.
Cutler, E. G., and Zollinger, R.: Atlas of Surgical Operations. 1939.
Dayton, N. A.: New Facts on Mental Disorder. 1940.
Drummond, J. C., *et al.*: Nation's Larder. 1940.

B.M.A.: Branch and Division Meetings to be Held

STAFFORDSHIRE BRANCH: NORTH STAFFORDSHIRE DIVISION—Joint meeting with North Staffordshire Medical Society. Sunday, February 2, 11 a.m. P. W. Edwards: Practical Hints on Wartime Food Problems.

WEEKLY POSTGRADUATE DIARY

EDINBURGH POSTGRADUATE LECTURES.—At Edinburgh Royal Infirmary, Fri., 4.30 p.m. Prof. R. J. S. McDowall: The Physiological Approach to Medical Problems.

DIARY OF SOCIETIES AND LECTURES

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—At Royal Society of Medicine, 1, Wimpole Street, W., *Mon.*, 3 p.m., Mr. F. Ronald Edwards, Dried Plasma: Its Preparation and Administration for the Syndrome of Shock.

ROYAL SOCIETY OF MEDICINE

General Meeting of Fellows.—Tues., 3.30 p.m. Ballot for election to Fellowship.

Section of History of Medicine.—Wed., 2.30 p.m. Paper by Dr. J. D. Rolleston: Medical Aspects of Saint Simon's Memoirs.

Section of Surgery.—Wed., 2.30 p.m. Presidential Address by Mr. J. B. Hunter: The Emergency Medical Service and the Future.

Section of Otology.—Fri., 10.30 a.m. Discussion: The Psychological Aspect of Deafness. Openers, Prof. H. Frey, Dr. A. B. Stokes, and Mrs. Irene H. Ewing.

Section of Laryngology.—Fri., 2.15 p.m. Discussion:—Adenoids: Their Influence and Methods of Removal. Openers, Mr. V. Negus, Adenoids: With Reference to Methods of Removal; Mr. W. Stark Adams, The Influence of Adenoid Infection on Nasal Sinusitis in Children.

APPOINTMENTS

BORHAM, J. D., M.R.C.S., L.R.C.P., Examining Factory Surgeon for the Southwold District (Suffolk).

BIRTHS, MARRIAGES, AND DEATHS

GEE-THAYSEN DISEASE

(IDIOPATHIC STEATORRHOEA OF ADULTS AND ADOLESCENTS IN NON-TROPICAL COUNTRIES)

BY

JOHN F. O'SULLIVAN, M.B., B.Ch.N.U.I.

Late House-physician, Mater Misericordiae Hospital, Dublin; House-physician, War Memorial Hospital, Scunthorpe

WITH A NOTE AND A POSTSCRIPTUM

BY

HENRY MOORE, M.D., D.Sc., F.R.C.P.I., F.R.C.P.Lond.

Professor of Medicine, University College, Dublin; Physician, Mater Misericordiae Hospital, Dublin

This disease, of which two cases are recorded here, has received considerable attention during the past decade. Coeliac disease was first described by Samuel Gee (1888) of London, and the condition as it occurs in adults and adolescents of non-tropical countries was first extensively studied by Thaysen (1929, 1932): hence the reason for the nomenclature, Gee-Thaysen disease, a name first suggested by Moore, O'Farrell, Geraghty, Hayden, and Moriarty (1936) and later supported by Mogensen (1937).

These two cases came under the care of Prof. Henry Moore in the Mater Misericordiae Hospital, Dublin, since the publication of the ten cases described by him and his co-workers in the paper mentioned above. Each has been fully investigated on the basis of the criteria then advanced. The recent work of Kantor (1939) has added what may prove another important diagnostic feature—i.e., roentgenological changes in the small intestine. These are (*a*) obliteration of the usual markings of the valvulae conniventes—the "moulage" sign: and (*b*) dilatation of the small intestine and segmentation of the contained barium into "clumps." In neither of our cases can it be said that Kantor's findings were discovered. In the previous series of cases from this hospital (Moore and others, 1936) three had duodenal abnormalities, and one of these (Case 4) showed "duodenal and jejunal delay with marked diminution of the typical markings of these bowel segments."

Treatment in both of our cases proved very gratifying. In this connexion the experiments of Barker and Rhoads (1937) are of interest. These authors concluded that in tropical sprue the parenteral administration of liver extract exerts some specific effect upon the absorptive power of the small intestine. Blood-fat determinations in sprue patients before and after liver therapy, with normal subjects as controls, support their conclusions. Snell (1939) reports that the appearance of the small intestine, as shown by roentgenological observation, was restored to practically normal by the parenteral administration of liver extract. In our second case satisfactory clinical response may have been to some extent influenced by the liver extract therapy, but this is doubtful.

Case I

An unmarried man aged 28 was admitted to hospital on November 7, 1938. The family history was negative. His own history was uneventful up to the age of 18, when he was treated for "glands in the neck," which disappeared. His present trouble began some months before admission with loss of appetite, lack of energy, and loss of weight, which he estimated at a stone and a half: at that time also he began to suffer from diarrhoea.

Physical Examination.—His weight was 93½ lb. and height 63¾ in. He was thin and pale, the tongue was too red and too clean, and papillae were scanty. Beard and moustache were absent. Examination of the lungs revealed some scattered rhonchi in both. The abdomen was slightly distended, while the descending colon was palpable and tender. The testicles were small: the pubic and axillary hair was scanty, and the former was feminine in distribution. Chvostek's and Trousseau's signs were negative and the clinical physical examination was otherwise normal.

Laboratory Investigations.—Blood chemistry (in mg. per 100 c.cm.): Serum calcium, 8.9: inorganic phosphorus, 3.1: urea, 42: cholesterol, 115. A blood examination showed 3,860,000 erythrocytes and 4,100 leucocytes per c.mm., with a normal differential leucocyte count: haemoglobin, 60%: and colour index 0.77. A blood smear revealed slight anisocytosis and poikilocytosis. A fractional test meal disclosed a very low curve of free HCl, the maximum being 16 units. The basal metabolic rate was −24%. The peroral glucose-tolerance test (ingestion of 50 grammes of glucose) gave the following results:

Time	Blood Sugar
Fasting	76 mg. per 100 c.cm.
In 30 minutes	85 " " " "
In 1 hour	83 " " " "
In 2 hours	63 " " " "
In 3 hours	61 " " " "

The curve was "depressed," the greatest increase of blood-sugar value being 9 mg. per 100 c.cm. (normal increase, 40 mg.). The faeces were light, clay-coloured, foul-smelling, and porridge-like. Microscopical examination did not reveal starch, undigested muscle fibres, or neutral fat: there was an excess of soaps, fatty acids, and other fat combinations, but no pus, blood, or mucus. On ordinary ward diet the weight of the stools averaged 40 oz. a day over a period of one week after admission. Chemical analysis of the twenty-four-hour stool (under ward dietary conditions) gave 46.23% total

lipoids, with normal fat splitting and a nitrogen output in the faeces of 8.34 grammes; the nitrogen figure, however, fell to a more normal one while the patient was under treatment. The results of the twenty-four-hour chemical stool analysis are summarized in the accompanying table, along with those of Case II.)

Table showing Chemical Analyses of 24 Hours' Faeces

Case	Date	Total Weight of Moist Stool	Dry Matter	Total Lipoids	Neutral Fat	Free Fatty Acid	Soap Fat	Total Lipoids	Neutral Fat	Nitrogen	Approx. Fat in Diet
		gm.	%	%	%	%	%	gm.	gm.	gm.	gm.
I	18/11/38	1,140	14.33	46.23	10.85	29.54	5.84	75.47	17.64	8.34	Full diet, 77
	17/1/39	653	9.02	58.53	9.72	21.35	27.47	34.48	5.70	3.02	
II	29/9/39	436	19.15	54.01	21.68	13.23	19.10	45.12	18.00	4.30	Full diet, 69
	3/11/39	203	16.47	20.18	6.26	12.02	1.90	7.06	2.05	1.96	

Roentgenological Examination.—No evidence of pulmonary disease was observed. There was a rapid passage of barium meal through the small intestine, and very marked redundancy of the large bowel with associated stasis and dilatation of the lumen due to intestinal gas. The epiphyses of the lower ends of the ulnae were not united to the shafts, while those of the lower ends of the radii, tibiae, and femora, and the upper ends of the tibiae were but partially united. A moderate degree of bony subcalcification was shown by controlled radiography of the hand. Barium enema examination emphasized the marked redundancy and dilatation of the colon; owing to the large amount of enema required to fill the entire colon it was considered inadvisable to fill the large bowel completely.

Examination of the eyes revealed normal refraction, and slit-lamp examination showed no abnormality of the lenses.

Treatment.—The patient was put on a low-fat diet consisting approximately of carbohydrate 218 grammes, protein 88 grammes, and fat 77 grammes per twenty-four hours. He was given 25 minims of dilute HCl with a little pepsin thrice daily by mouth after meals, and daily in addition, orally, 9 grains of ferrous sulphate, 40 grammes of calcium gluconate, 25 mg. of calciferol, and a vitamin preparation which furnished a daily intake of 18,600 international units of vitamin A, 150 international units of vitamin B_1, 30 Sherman units of vitamin B_2, 600 international units of vitamin C, and 2,700 international units of vitamin D. Under this treatment the bulk of the faeces was reduced considerably: over a period of two weeks before discharge they averaged about 22 oz. a day. Diarrhoea was completely relieved and steatorrhoea was reduced from 75.47 to 34.48 grammes of total lipoid per twenty-four hours (see table). Nine weeks after admission the blood count showed: erythrocytes, 3,800,000 per c.mm., haemoglobin 70%, and colour index 0.92. The patient left hospital on the above treatment on January 25, 1939.

Re-examination on July 20, 1939, after approximately six months of this treatment at home, showed a gain in weight of 30¼ lb. and an increase in height of almost one inch (2¼ cm.); the axillary and pubic hair was more plentiful, but the latter was still feminine in distribution. The patient had had no diarrhoea since his stay in hospital and he stated that he felt, and he certainly looked, extremely well. There was apparently no anaemia (no blood count was done). He was seen again in May, 1940. For the previous twelve months or so his only treatment was a low-fat diet. His weight was approximately 10 stone, and he reported that he felt well, was able to do a full day's manual labour on a farm, and had no diarrhoea, the stools being well formed and normally coloured. The pubic and axillary hair had increased, and he stated that libido was present. A test meal was normal and the blood count showed 4,210,000 erythrocytes and 101% of haemoglobin. He certainly looked in very good health.

Summary.—A man aged 28 suffering from diarrhoea, lack of energy, loss of appetite, loss of weight. Examination showed a mild hypochromic anaemia, moderate bony subcalcification, ununited epiphyses, infantilism, and steatorrhoea. Treatment with a low-fat diet, iron, and vitamins produced striking improvement clinically, a gain in weight of more than 3 stone, and an increase in height of 2¼ cm.

Comments on Case I

1. The diagnosis of Gee-Thaysen disease might seem to be in doubt because of the high faecal nitrogen (8.34 grammes). This would suggest pancreatogenous steatorrhoea: Thaysen (1932) considered that a faecal nitrogen which much exceeds 3 grammes daily indicates this latter condition. The faecal nitrogen estimation in the present case was reported on four occasions during the next fortnight, with the following results: 3.58, 4.19, 4.68, and 3.65 grammes. These figures are considerably lower than the first analysis, although still somewhat above Thaysen's figure; but when considered with the "flat" type of blood-sugar curve, the absence of muscle fibres in the stools, and the clinical course of the case, the diagnosis of pancreatogenous steatorrhoea may be discarded.

2. After reduction of the fat intake the percentage of lipoid in the faeces did not become reduced; indeed, it increased from 46.23% of the total dry matter to 58.53%. Nevertheless, although the percentage of total lipoid did not fall on treatment, the amount of lipoids in the stools by weight fell from 75.47 to 34.48 grammes, and of neutral fat from 17.64 to 5.7 grammes—a drop of 55% and 70% respectively. The effect of curtailment of fat on the faecal lipoid output was considered by Moore and his co-workers (1936) in the previous series of cases studied in this hospital; it was concluded that usually the percentage of lipoid in the faeces varied directly with the fat intake. Nevertheless inconsistent results were obtained (Cases 6 and 10) in which the percentage output was greater after the restrictions in the diet. Bennett, Hunter, and Vaughan (1932) made a special investigation of this point on one patient (Case 1); they found that the percentage faecal output was reduced with a low-fat diet although even then on the average the fat comprised more than 25% of the dried faeces. Clinically in the present case the fat-poor diet controlled the diarrhoea, although it cannot be exactly stated to what extent fat absorption was influenced by the treatment.

3. At 28 years the patient increased in height by almost one inch (2¼ cm.). Epiphyses were ununited before treatment began. Two cases in the series reported by Moore *et al.* (1936) (Cases 4 and 7, aged 22¾ and 19 years) also increased in height while under treatment. Thaysen suggested that hypovitaminosis of the fat-soluble vitamin A is an important factor in causing the infantilism of this disease. Mogensen (1937) investigated one patient for vitamin A deficiency according to the method of Edmund and Clemmesen (1936), and he concluded that there was probably a deficiency even though there were no clinical signs. He suggested, therefore, that therapy should include regular administration of vitamin A. In patients with ununited epiphyses this ought to be particularly valuable. In the present case 18,600 international units of vitamin A were given daily.

Case II

A male aged 19 was admitted to hospital on September 21, 1939, with the complaint that he had not increased in weight during the previous two years despite an inordinate appetite. For four years he had been treated for anaemia with liver orally and later on with liver extract. He was listless, easily fatigued, and disinclined for any considerable exertion. He stated that for as long as he could remember he had had diarrhoea (three to four motions a day), with the exception of an interval of three years at a boarding-school when apparently he was unwittingly being treated by a low-fat diet. With the exception of bronchopneumonia at the age of 2 years there had been no other serious illness, and the family history was not significant.

Physical Examination.—The patient was emaciated and markedly underdeveloped. His height was 64½ in. and weight 91½ lb. Anaemia was pronounced and there was a brownish pigmentation over the malar regions; beard and moustache were absent. The abdomen was distended and tympanitic, the testicles were small, the pubic hair was scanty and feminine in distribution, and the axillary hair was also scanty. The papillae on the tongue were small and few, the tongue itself was too red and too clear, and the mucous membrane was atrophic. As regards bony structure, he was lightly built, genu valgum was present, and the lower thorax was unduly expanded, so that the subcostal angle was practically 160 degrees. Blood pressure was 110/52. Auscultation of the heart revealed blowing systolic murmurs at apex and base. Intellectually the patient was alert and had reached an honours standard in the school examinations. The clinical physical examination was otherwise normal.

Laboratory Investigations.—Blood chemistry (in mg. per 100 c.cm.): urea 30, serum calcium 8.8, inorganic phosphorus 3, blood cholesterol 140. Blood count: erythrocytes 2,190,000 per c.mm.; haemoglobin 30%; colour index 0.68. Anisocytosis and poikilocytosis were pronounced and there were a number of macrocytes. A fractional test meal showed almost complete achlorhydria—3 units of free HCl were present in only one specimen. The basal metabolic rate was − 17%. The peroral glucose-tolerance test (ingestion of 50 grammes of glucose) showed:

Time	Blood Sugar
Fasting	71 mg. per 100 c.cm.
½ hour after ingestion	118 " " " "
1 " "	85 " " " "
2 hours "	75 " " " "
3 " "	77 " " " "

The curve was "depressed" in type. The faeces were pale, soft, rather foul-smelling. Microscopical examination showed excess of fatty acids, soaps, and other fat combinations, but no further abnormalities. The weight of the twenty-four-hour stool over several days averaged about 8 oz. Chemical examination of the twenty-four-hour specimen showed 54.01% total lipoids—21.68% neutral fat and 32.33% of total split lipoids. The total faecal lipoid output was 45.12 grammes per twenty-four hours—nearly four times the average normal output. Faecal nitrogen amounted to 4.30 grammes. The details of these analyses are compared in the table with the result of a similar analysis performed when the patient had been on a low-fat diet for five weeks.

Roentgenological examination showed no evidence of pulmonary disease, and there was some bony subcalcification with all the epiphysial lines unusually open for a subject of 19 years. A radiograph of the gastro-intestinal tract showed gastro-intestinal hypermotility and redundancy of the distal colon. *Slit-lamp examination* disclosed no abnormality in the lenses.

Treatment.—The patient was put on a diet of approximately 339 grammes carbohydrate, 95 grammes protein, and 69 grammes fat. His appetite was enormous, and even on this regime, with a caloric value of approximately 2,300, he complained of hunger. Accordingly he was allowed bread *ad lib.*, which enabled him to satisfy his appetite without appreciably raising his fat intake. In addition he was given 30 minims of dilute HCl three times daily after meals, 9 grains of ferrous sulphate daily, and a vitamin preparation which supplied daily 18,600 international units of vitamin A, 150 international units of vitamin B_1, 30 Sherman units of vitamin B_2, 600 international units of vitamin C, and 2,700 international units of vitamin D. The patient was also given four courses of liver extract intramuscularly, each course consisting of 2 c.cm. daily for three days; this, however, was probably unnecessary.

Symptomatic improvement was rapid on this treatment. The number of daily motions was reduced from three during the first week to one thereafter, and the faeces became formed and much less objectionable in smell, but there was no significant alteration in their weight. Great improvement was shown after treatment (see table). The basal metabolic rate changed from − 17% on September 30 to + 3% on November 11. There was no increase in height while under observation, but the patient put on 17 lb. in fifty-nine days. A fractional test meal after five weeks' treatment and after one year from discharge showed complete achlorhydria.

The anaemia rapidly disappeared, and this improvement was accompanied clinically by the disappearance of the heart murmurs and a striking change in the patient's appearance. From one who seemed stricken with a serious wasting illness he was transformed into a lively, healthy-complexioned youth. For the past year the only treatment was the low-fat diet and 25 minims of dilute HCl with a little pepsin thrice daily after meals, but improvement continues to be well maintained. On September 30, 1940, his health was excellent, he had gained 33 lb. in weight and 2 in. in height. He is now an active healthy medical student. For the past two months he has done equally well without the hydrochloric acid.

Summary.—An emaciated male aged 19 years with a long history of diarrhoea, suffering from lack of energy and inability to increase in weight. Examination showed a slight degree of hypocalcaemia, some bony calcification, steatorrhoea, infantilism, non-union of epiphyses, and a severe degree of anaemia. Treatment produced a most satisfactory clinical response.

Comments on Case II

1. The high percentage of neutral fat requires consideration. Fowweather (1926) states that (*a*) where neutral fat exceeds 11% of the dry matter one should suspect defective fat splitting; (*b*) if the total split lipoid exceeds 16% of the dry matter one should suspect deficient fat absorption. In this case neutral fat was 21.68% of the dry matter, and the total split lipoids (soaps and fatty acid) were 32.33%—an apparent combination of deficiency of both fat absorption and fat splitting. In four of the cases of Bennett, Hunter, and Vaughan (Cases 5, 6, 8, 9) there was a similar marked abnormality in the percentage of neutral fat; in Case 8 this amounted to 45.2% of the dried matter. The total lipoid percentage in all those cases was very high—over 50. The probable explanation—accepting Fowweather's criteria—is that in such cases there is a degree of deficient fat splitting, not due to any organic pancreatic disease. Probably the defective fat splitting is due to the rapid rate at which the food passes through the intestine and the consequent failure of the pancreatic ferments to exert their full action. In the present case, after treatment was instituted the percentage of neutral fat in the stools fell to 6.26%, a figure well within the normal limit.

2. The proportion of total lipoid in the stools after limitation of fat intake fell from 54.01 to 20.18%. In Case I limitation had the opposite effect on the percentage of total lipoid. In both cases, however, the actual amount of total lipoids and neutral fat fell sharply after treatment.

3. Two features in the treatment of Case II are of interest. Four courses of liver extract intramuscularly were given. As mentioned previously, some American workers have used liver extract alone in treatment for its supposed specific effect on the absorptive power of the mucous membrane of the small intestine, and without any reference to the blood picture. Mogensen (1937) justifies the use of liver extract injections in one of his cases with a hypochromic anaemia because of a decrease in the number of red cells together with the presence of megaloblasts. The blood picture in the present case was somewhat similar to that in Mogensen's case. The rapid response to treatment in Case II may possibly to some extent be due to this liver therapy.

The other feature of interest in the treatment concerns the amount of protein in the diet. Weir and Adams (1935) recommend a protein allowance higher than normal because the haematogenous "extrinsic factor" is contained in protein food and because there is frequently a negative nitrogen balance in Gee-Thaysen disease. Thaysen (1935)

declared that a relatively high nitrogen intake was essential for the maintenance of a positive nitrogen balance in idiopathic steatorrhoea; in a series of experiments on patients he maintained a positive balance on diets with a daily protein equivalent of 80 to 90 grammes. In both of our cases an allowance of about 2 grammes of protein per kilogramme of body weight was made, which meant that each patient received approximately 90 grammes of protein daily. A liberal protein intake is therefore apparently advisable in treatment.

I wish to express my thanks to Prof. Henry Moore for his suggestion to publish these two cases and also for his invaluable advice and criticism in the preparation of this paper.

PROFESSOR MOORE'S OBSERVATIONS

Little is known of the pathogeny of this interesting but complex disease. My own view is that in the great majority of cases the fundamental fault lies in imperfect absorption from the small intestine; in a small minority, however, lacteal obstruction may possibly play a part. The most important factor in the causation of the symptoms would seem to be imperfect lipoid absorption: the presence of the abnormal amount of lipoids in the bowel would appear to be to a large extent responsible not only for the diarrhoea but also for the imperfect absorption of calcium, phosphorus, haematopoietic bodies, and vitamins, in varying degrees in different cases. This view is supported by the following observation. We have been able to follow eleven of our twelve cases for from fourteen months to fifteen years—seven of them for over five years and two for over three years. After the initial period of some months on low-fat diet and "replacement" therapy seven of them remained in quite good health for prolonged periods on the low-fat diet alone. In addition to the low-fat diet, one took calcium gluconate, one took a few daily drops of haliverol, one had occasional doses of marmite, and one had occasional doses of dry vitamins; all four continued well for years. It is probable, therefore, that the chief factor in the production of disability in the Gee-Thaysen disease is the abnormally increased lipoid content of the bowel due to malabsorption of lipoids by the small intestine.

In the paper by Bennett, Hunter, and Vaughan (1932) it is stated that in adult and adolescent cases of idiopathic steatorrhoea the results of treatment in general are more disappointing than in children suffering from coeliac disease, and that, although some cases respond more satisfactorily than others, in the majority all that is accomplished is the alleviation of one or more symptoms and the temporary arrest of downward progress. Our experience, on the contrary, is that the results of treatment are most satisfactory, and this notwithstanding the fact that six of our twelve cases could be classified as very severe and four as severe; three of them had multiple pathological fractures, all of which healed under treatment. Of our twelve patients one died of the disease itself—this was a case seen in 1926 (Case 2 in our original paper), when we were not in a position to carry out the successful treatment elaborated later; one died of acute lobar pneumonia in 1936, but for three years from discharge enjoyed excellent health; and one died of pulmonary tuberculosis, symptoms of which appeared three and a half years after discharge from hospital. Of the nine cases surviving to date the results can be stated to be excellent in six (of which one was observed for fourteen months, one for two years, and the remaining four for from five to fifteen years) and good in three (all of these three cases were observed for over five years).

Accordingly, our belief is that treatment—which in the initial stages should be carried out in hospital, which must be individualized, and which may have to be continued for considerable periods—gives on the whole very satisfactory results.

POSTSCRIPTUM

Since the above note was written a paper by Bennett and Hardwick (1940) has appeared in which these authors, in relation to cases of "non-tropical sprue" in adults, state: "We find no justification for classing such cases with coeliac disease or for describing them, as has been done by H. Moore *et al.* (1936) and E. Mogensen (1937), as Gee-Thaysen disease." "This situation is not improved by the endeavour of Moore and others to identify the infantile cases with those appearing in later life to the exclusion of the tropical cases, for the cases arising in adult life resemble the tropical cases closely, but have only superficial resemblance to the infantile and adolescent ones."

It was precisely to bring out the difference between the infantile and the adult cases that we proposed the name Gee-Herter disease for the former and Gee-Thaysen disease for the latter. There are certain resemblances between the infantile and the adult cases, but there are also differences even whether the adult cases persist from infancy into adult life or arise in adult life: these symptomatological differences are probably due largely to the different age incidence and to the different mode of life led by the adult as compared with the child. Many adult cases in some respects resemble tropical sprue, but many do not—e.g., some cases of "non-tropical sprue" apparently beginning in adult life show marked osteomalacia and even fractures, whereas such conditions are not, so far as I am aware, found in tropical sprue. So far as I can understand their paper Bennett and Hardwick seem to wish to establish the close resemblance between cases of idiopathic steatorrhoea beginning in adult life and cases of tropical sprue. Resemblances there certainly are, but there are also notable differences. For example, as reported in our paper (Moore *et al.*, 1936), Cases 1, 5, and 10 (aged respectively 28, 29, and 63) had marked osteomalacia, with fractures in Cases 1 and 5; yet the onset, so far as could be judged from the history, did not begin in childhood and the symptoms did not closely resemble sprue. On the other hand, in Case 2 (aged 43), which did resemble sprue, the onset was probably in adult life, whereas in Case 6 (aged 40), which also resembled sprue, loose motions had been present since childhood. Again, Case I of the present paper did not resemble sprue, and the onset, judged by the roentgenological appearances of the bones, may have begun at about early adolescence, but could not be traced back to childhood.

The point raised by Bennett and Hardwick seems to be the nomenclature of those cases of "idiopathic steatorrhoea" which appear first in infancy and persist until adult life, and of those which first appear in adult life: are the latter more allied to tropical sprue than to coeliac disease? I confess that I do not believe we have enough exact information to give a definite answer to this question. There seems to be little doubt that the one aetiological factor running through (*a*) coeliac disease, either in infancy or persisting to adult life, (*b*) "idiopathic steatorrhoea" beginning in adult life, and (*c*) tropical sprue is, as Bennett and Hardwick put it, chronic jejunoileal insufficiency; but the manifestations of this deficiency might be different according to the age of the patient, the time of onset, the duration of the deficiency, the environment of the sufferer, and other factors. With a common fundamental defect it might not always be easy to say whether an adult case was more closely allied to tropical sprue than to infantile coeliac disease.

Gee (1888), describing the coeliac affection, wrote (italics mine): "There is a kind of chronic indigestion which is met with *in persons of all ages*, yet is especially apt to affect children between 1 and 5 years old"; and again: "The coeliac disease is commonest in patients between 1 and 5 years old; it often begins during the second year of life. Sometimes from India Englishmen return sick with the coeliac affection: seldom is it met with *in adults* who have never left our island." Gee therefore was almost certainly aware of the existence of adult cases of "non-tropical sprue" as well as of the infantile cases of coeliac disease and of tropical sprue. Tropical sprue was described before Gee's time. Gee's original paper was apparently forgotten until in 1906 Herter, in the U.S.A., gave a good account of the disease in children. Thaysen gave excellent descriptions of adult cases of idiopathic steatorrhoea in 1929 and 1932. With these facts in mind my co-workers and I (Moore *et al.*, 1936) wrote as follows:

"In the interest of clarity, and in order to give credit to those observers who have been chiefly instrumental in the recognition, description, or separation of these three interesting disease entities, we suggest that coeliac disease of children be called the Gee-Herter disease, that idiopathic steatorrhoea as it occurs in adults and adolescents of non-tropical countries be called the Gee-Thaysen disease, and that the name sprue be retained for the disease as it occurs in adult residents of tropical countries. It may be that a better nomenclature will become apparent as the obscurity at present surrounding the pathogeny and aetiology of the idiopathic steatorrhoeas becomes more clear. The name idiopathic steatorrhoea is not a suitable one, for steatorrhoea is common to all three and the term *idiopathic* is simply a *teleological confession of* ignorance; steatorrhoea, also, occurs under other conditions."

Bennett and Hardwick would probably argue that it is wrong to use the name Gee-Thaysen disease with reference to an adult case in which the disease began many years back in childhood and persisted into adult life, as well as for the case in which the malady first appeared in adult life or middle age; on the other hand, the symptomatology may not be quite the same in infancy as in adult life, even in those cases in which the disease originated in infancy and with persistence of symptoms into adult life, although not infrequently the resemblance may be close. In the latter case it is admittedly not wholly desirable to call a disease of infancy by one name and to use another when it persists to a later age. While we await the further information necessary for a final nomenclature Gee's name can be attached to both; in the infantile cases the name of Herter and in the adult cases that of Thaysen could be added to denote the changing symptomatology coincident with increasing age.

I. S. Cormanschi (*Thèse de Paris*, 1940, No. 252), who records three cases in patients aged from 19 to 29, one of which is original, describes a disease characterized by the triad of iritis, genital ulceration, and buccal aphthae. The aetiology is still obscure. Recurrent iritis with hypopyon is found in both sexes. The genital ulcers and buccal lesions are slight. The ocular lesions as a rule consist not only of iritis or iridocyclitis but also of uveitis.

BLOOD AND PLASMA TRANSFUSION IN ALIMENTARY HAEMORRHAGE

BY

D. A. K. BLACK, M.D., M.R.C.P.
Beit Memorial Research Fellow

AND

A. FORD SMITH, B.M., M.R.C.P.
(From the Nuffield Department of Clinical Medicine, Oxford)

The infusion of serum or plasma has been shown to exert a favourable effect not only in experimental shock in animals (Bond and Wright, 1938; Mahoney, 1938; Best and Solandt, 1940) but also in shock from burns (Trusler *et al.*, 1939) and wound shock (Edwards *et al.*, 1940) in the human subject. It has been argued that even in acute haemorrhage the absolute deficiency of red cells is of less importance than the vascular and circulatory derangement which prevents the effective access of blood to the tissues, and that the improvement of circulation following plasma infusion would outweigh the reduction in the number of red cells per unit volume of blood. If this were the whole story the ready availability of stored plasma and the absence of delay required to group the recipient would render it a valuable preliminary treatment of haemorrhage, even if it were necessary to give whole blood at some later time.

The object of this paper is to compare the effects of citrated whole blood with those of plasma in treating patients with massive bleeding from the stomach or duodenum. For a study of this type patients with haematemesis and melaena offer the advantages that the lesion causing haemorrhage is uniform in type, enabling a fair comparison to be made: reasonably good quantitative indications of the severity and progress of the case are given by measurements of the blood volume (Bennett *et al.*, 1938) and blood urea; and the indications for transfusion are comparatively definite. These last have been summarized by Witts (1937) as a pulse rate above 140, systolic blood pressure below 90 mm., blood urea above 100 mg. per 100 c.cm., or haemoglobin lower than 40%.

Clinical Material and Methods

The nine patients studied were all suffering from severe bleeding from the stomach or duodenum, and were kept at rest in bed on an adequate intake of food and fluid in the form of two-hourly feeds of milk and cream, with added vitamins. The first three were treated with massive transfusion of citrated blood by slow drip, and in one of them three transfusions of a litre or more were given. The fourth patient was treated with reconstituted dried serum in fourfold strength, but showed so severe an immediate reaction that this experiment was not repeated. In Cases 5 and 6 plasma infusion was started, but had to be supplemented straight away by blood transfusion; in Cases 7, 8, and 9 it was possible initially to give plasma alone, by slow drip, although Case 8 required whole-blood transfusion five days later. The plasma used was obtained by allowing blood of Group AB to stand in M.R.C. citrate bottles for forty-eight to seventy-two hours at 4° C., and aspirating the plasma into clean bottles with sterile precautions; it may be of importance that plasma so obtained is diluted bulk for bulk with citrate solution, and it may perhaps be best described as half-strength plasma.

In addition to observations on the general state of the patients, estimations of the blood urea were carried out

at intervals of a few hours on finger-prick blood, using the micro-method of Archer and Robb (1925); blood volume was estimated by the vital red method.

Haematological Findings

Whole-blood Transfusion.—The giving of whole blood is followed by an increase in the total amount of circulating red cells, as calculated from the plasma volume, directly determined by the dye method, and from the haematocrit on venous blood. The increase in red cell volume may correspond closely to the mass of red cells given in the transfused blood, as in Case 1, in which the cell volume increased by 0.4 litre after a transfusion of 0.8 litre of blood containing 0.35 litre of red cells. On the other hand, deviations from this conformity are sometimes greatly in excess of the limits of error of the method used—as carried out in normal subjects—where estimations on several consecutive days have agreed within ±0.1 litre. It is possible to account for instances in which the observed increase in red cell volume is less than the amount of red cells supplied by postulating continued haemorrhage, other signs of which may be present, such as rising pulse rate or fall in blood pressure. In Case 3, however, a transfusion containing 0.4 litre of red cells was followed by an apparent rise in red cell volume to 0.7 litre, a discrepancy which may be accounted for in the following way. The accuracy of the calculation of red cell volume depends on the extent to which the venous haematocrit reading is representative of the cell: plasma ratio in the whole mass of circulating blood: in conditions of shock, haemoconcentration may be present in the capillaries (McDowall, 1940), so that the plasma: cell ratio in the veins is higher than in the blood stream as a whole. In these circumstances the value for total blood volume, derived from the expression

$$\text{Blood volume} = \frac{\text{plasma volume}}{\text{venous plasma : whole blood ratio}},$$

is low, so that the first estimation of red cell volume is probably too low; while the second, made after the shock has been treated by transfusion, is more accurate, and the difference between the two estimations is thus accentuated in patients in whom capillary haemoconcentration has been prominent.

The changes in plasma volume after transfusion of whole blood are largely dependent on the extent to which the restoration of blood volume by plasma dilution has progressed by the time transfusion is carried out. When the plasma volume before transfusion has already risen to a normal amount, as in Case 1, little further increase is observed; but when dilution is incomplete before transfusion, as in Case 3, increase in plasma volume is observed even in excess of the volume of added plasma, since the improvement wrought in the circulation by transfusion enables the normal process of dilution to proceed at a more rapid rate. These findings are in accordance with the observations of Bock (1921) on the tendency to maintain or restore a normal plasma volume under widely differing conditions. The haematocrit and haemoglobin percentages and the red cell count were found to be raised in all cases when blood was given.

Serum or Plasma.—In the four patients to whom serum or plasma alone was given increments in plasma volume occurred. In No. 7, who had pronounced ill effects after the plasma infusion, the increase in plasma volume was 900 c.cm.—almost equal to the litre of plasma given; in Cases 8 and 9 the increase in plasma volume was only about half the amount of plasma given, and in them the ill effects were less severe. In No. 4, who received 140 c.cm. of four-times-normal serum, the increase in plasma volume was 300 c.cm., showing that some dilution had occurred: as it was not possible to estimate the blood volume immediately after the injection it is probable that dilution was complete but that some fluid was lost thereafter. In all four patients the estimated red cell volume after plasma infusion was within 100 c.cm. of the value obtained before infusion; there is therefore no evidence that plasma infusion in these patients effected any mobilization of red cells from the tissues, as it has been claimed to do (Brennan, 1940). Reduction of haematocrit percentage, haemoglobin concentration, and red cell count was found in the patients treated with plasma, and regeneration to the normal count from this lowered level appeared to be slower.

Blood Urea

The causes of the rise in blood urea observed after severe alimentary haemorrhage have been discussed at some length in another paper (Black and Leese, 1940); for our present purpose it is sufficient to state that the degree of elevation of blood urea bears a fairly close relation to the severity of illness, and that clinical improvement is accompanied by decline in the blood urea. A fall in blood urea after massive transfusion in haematemesis was observed by Wood (1936); but the changes in blood volume over the same period were not studied.

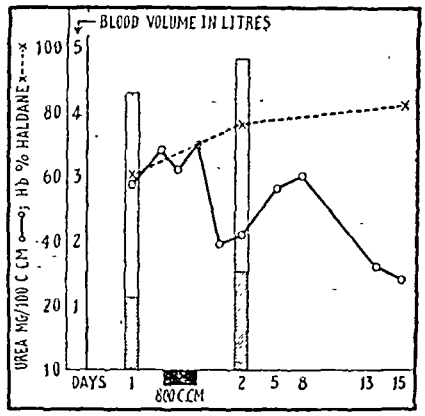

FIG. 1.—Blood volume, haemoglobin, and urea before and after blood transfusion in Case 1. The shaded area represents the total red cell volume.

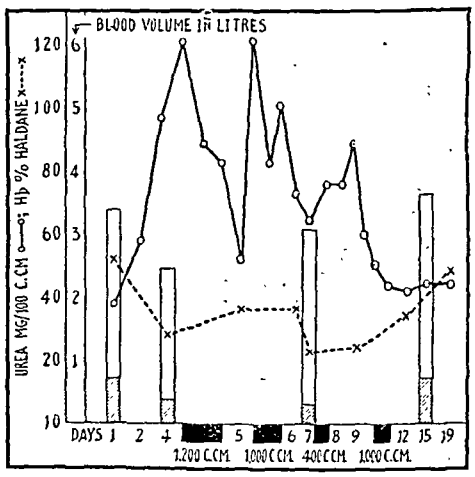

FIG. 2.—Blood volume, haemoglobin, and urea in relation to repeated blood transfusions in Case 2.

Whole-blood Transfusion.—The results in our patients, including those to whom blood had to be given after plasma, show that a fall in blood urea occurred after each of eight large transfusions of whole blood, carried out on six subjects; two other patients have shown a definite fall in blood urea after transfusion with citrated blood, but

are not included in the present series, since evidence of renal damage persisted after the acute haemorrhagic episode. In four of the eight transfusions here reported the blood urea was rising when transfusion was started, so the subsequent decline is not likely to have been spontaneous; moreover, it occurred with much greater rapidity than the decline in blood urea which is usually observed a few days after the haemorrhage. The time relation between transfusion, blood-volume increase, and decline in blood urea can be best seen in Figs. 1 and 2. A small and transient decline in blood urea was sometimes seen during the actual course of the transfusion, as in Cases 1 and 3 and in the second transfusion of those given in Case 2; but the major and lasting decrease in blood urea followed rather than accompanied the transfusion. The initial slight fall in blood urea may perhaps be attributed to dilution of azotaemic blood with blood of normal urea content; its transient nature can be accounted for by the rapidity with which urea diffuses from the tissues into the blood stream. The important fall in blood urea which occurs after the transfusion cannot be ascribed to dilution, and we believe that it depends on the increase in blood volume, which improves renal function, facilitating the removal of urea from the blood stream.

Serum or Plasma.—Four patients were treated with plasma or serum without any subsequent blood transfusion; in No. 4, who was given serum, the blood urea rose just after the transfusion, but fell slowly to normal in the next few days. In Case 9 the blood urea had fallen almost to normal before plasma was infused, and no further rise occurred. Cases 7 (see Fig. 3) and 8 each

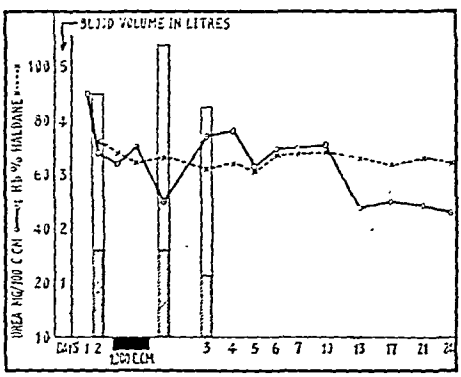

FIG. 3.—Blood volume, haemoglobin, and urea before and after plasma infusion in Case 7.

had azotaemia for more than five days after the infusion, in contrast with patients who had been given whole blood, and even with patients left to recover spontaneously from haematemesis. Plasma and serum therefore did not produce the same rapid fall in blood urea as did transfusion of whole blood.

General Effects

The beneficial effects of whole-blood transfusion in patients who have lost blood are well known. In the six patients who were given plasma immediate subjective or objective clinical improvement was absent; all showed some harmful effect, and in two of them the reaction was so severe that massive blood transfusion had to be used at once. The chief complaints during plasma infusion were of headache, faintness, and a vague sense of irritability. Objectively, increase in pallor, quickening pulse, and drowsiness leading to actual unconsciousness were noted; in the first patient, who had a low haemoglobin at the outset, unconsciousness persisted for over half an hour. Even after recovery from the immediate effects of plasma transfusion clinical improvement, and especially blood regeneration, were notably slower than in the patients to whom whole blood had been given; No. 4, who had serum, and whose plasma volume increased only by 300 c.cm., was an exception to this.

Discussion

Our experience has been that in patients suffering from alimentary haemorrhage plasma has not only been of no value as a substitute for whole blood in therapy, but has given rise to untoward and even dramatic ill effects. We have used plasma prepared in the same way in the treatment of burn shock, with good results and with no adverse reaction; it is therefore unlikely that any inherent defect of the plasma is responsible for the unsatisfactory response of patients with haemorrhage. Such patients are distinguished from patients with burn shock, who respond well to plasma, by the low content of haemoglobin in the blood. The most obvious effect of giving plasma is to increase the dilution of the formed elements in the blood, so that blood volume is increased at the expense of haemoglobin concentration. In this connexion the observations of Robertson and Bock (1918) in the war of 1914–18 are of great significance. They found that when the haemoglobin was below 40 to 50% spontaneous blood dilution did not occur; it seemed, in fact, that maintenance of haemoglobin at such a level was of more importance to the organism than restoration of the blood volume to full normal limits. It is reasonable to ascribe the ill effects of plasma infusion in patients with severe haemorrhage to the rapid and forced dilution of the blood to a greater extent than would naturally occur in response to haemorrhage. This interpretation is supported by the very rapid appearance of ill effects in patient No. 4, who received fourfold serum, and in whom blood dilution was likely to have occurred even more rapidly than with ordinary plasma.

It must be emphasized that plasma is of great value in the treatment of shock from such causes as burns and intestinal obstruction; when, however, shock is associated with a degree of haemorrhage sufficient to lower the haemoglobin percentage by a half or more, our results suggest that the giving of plasma is contraindicated, even as a temporary measure pending whole-blood transfusion. This conclusion does not conflict with the favourable results reported by Brennan (1940), since the lowest red cell count in his series was 2.99 millions: there is a stage of post-haemorrhagic shock, before blood dilution has occurred, when plasma infusion seems to be of value. When, however, the haemoglobin has fallen to 50% or less, as happens in many cases before the patient comes under observation, the time for plasma is past, and benefit will be obtained only from transfusion of whole blood. The practical recommendation we would wish to make is that any patient who is known to have bled should only be given plasma if the haemoglobin percentage is over 50; otherwise there is a risk of serious collapse, which may demand for its treatment an amount of whole blood larger than would have been required in the first instance. On the other hand, in recent haemorrhage, when dilution is slow on account of shock and the haemoglobin percentage remains high, plasma infusion is beneficial, as shown by the results of Brennan (1940) in patients and of Buttle *et al.* (1940) in animals.

Case Protocols

Case 1: Bleeding Peptic Ulcer.—This patient, a man aged 48, had had vomiting and dyspepsia for three weeks before admission for haematemesis on August 14, 1939. He was pale and shocked, with a blood pressure of 100/50, pulse rate 110, and temperature 98.4°. After transfusion of citrated blood, carried out on the day of admission, his blood pressure

became 110/70, and remained at this level. His pulse rate dropped to 80. Although he had a pyrexia of 102° F. on the day after transfusion his general condition was much improved. He made a good recovery, but had to be evacuated from hospital before full investigation had been carried out. The results of blood examination are as follows, and are also represented in Fig. 1.

Date and Time	Plasma Volume (litres)	Haema-tocrit %	Blood Volume (litres)	Blood Urea (mg./100 c.cm.)	Haemo-globin % (Haldane)	R.B.C. (millions per c.mm.)	W.B.C. per c.mm.

28/8/39				28	82		

Case 2: Bleeding from Gastric Ulcer.—The second patient, a woman aged 43, had had dyspepsia since 1926; gastro-enterostomy was done in 1929 for duodenal ulcer. She was admitted on September 25, 1939, having vomited blood repeatedly on that and the previous day. She continued to vomit in hospital, and her blood pressure, which had been 180/100 on admission, fell to 95/30 on the 29th, while her pulse rate rose from 90 to 130. She was given repeated transfusions of citrated blood, as detailed below, and showed temporary improvement after each, though she did not stop vomiting until October 4. A barium meal showed an ulcer high up on the lesser curvature, and this appeared at gastroscopy on November 1 to be in process of healing. The effect of the transfusions is indicated by the results given below and in Fig. 2; it is of interest that the small infusion of 400 c.cm. of blood produced no lowering of the blood urea.

Case 3 Bleeding from Gastric Carcinoma.—Although dyspepsia had been present for seven years in this patient, a man aged 60, his pain had become more constant and severe in the month preceding his admission on November 6, 1939. He had small haematemeses while in hospital, but the first massive bleeding occurred on December 4, when he had three haematemeses of upwards of a pint each, and became pale, with a feeble pulse, the rate being 120 per minute. He was given a transfusion of a litre of citrated blood, with great improvement in his general state and a fall in the pulse rate to 80. A barium meal on December 19 showed the presence of a large mass involving the body of the stomach.

Case 4: Gastric Erosion.—This patient, a man aged 44, was admitted on May 10, 1940, after repeated small haematemeses which began the previous day. He was pale and shocked, with a pulse of 144 and a blood pressure of 82/60; epigastric tenderness was present. Two hours after admission reconstituted dried serum in fourfold concentration was given intravenously by syringe at a rate of 10 c.cm. a minute. After five minutes respiration quickened and deepened, the patient became restless, and he vomited twice. After 140 c.cm. had been given a convulsion occurred and the injection was stopped. For the next half-hour he was collapsed and semi-conscious, but could be roused. He was well on the following morning, apart from slight backache. The residue in the bottles used was found to be sterile. On May 11 his blood pressure was 114/65 and the pulse rate 98. Subsequent recovery was uneventful.

Case 5: Bleeding from Gastric Ulcer.—This patient, a man aged 38, was transferred from a cottage hospital, where he had been under treatment for haematemesis for six weeks. On admission to the Radcliffe Infirmary his pulse rate was 120, blood pressure 60/40, and haemoglobin 18%, and he appeared to be in shock. In spite of the low haemoglobin it was decided to give him plasma, since a good supply of compatible blood was available if his response to plasma were poor. After 300 c.cm. of plasma had been given at the rate of 200 c.cm. an hour he became unconscious, following some preliminary restlessness, and a change-over to blood was made. He then improved rapidly, and his blood urea fell in the usual fashion, as shown below. He was later transferred to a surgical ward, where gastro-enterostomy was done for relief of pyloric obstruction caused by a chronic gastric ulcer.

Case 6: Duodenal Ulcer.—This man, aged 58, had several haematemeses on August 6, 1940, and was admitted the next day at noon. He was pale and slightly cyanosed, with blood pressure 125/75 and pulse 146. A plasma infusion was begun, but the patient became restless and irritable, and looked much worse. Oxygen was administered with the B.L.B. mask, but did not appear to arrest the deterioration in his condition. His blood pressure fell to 100/46, and after a pint of plasma had been given a change-over to blood had to be made, and this was followed by the usual improvement. On August 8 his pulse was 100 and blood pressure 122 56. Recovery was normal, and he was discharged on September 20.

Case 7: Bleeding from Gastric Ulcer.—This man, aged 59, had had dyspepsia of gastric ulcer type since 1917; he had had slight haematemesis and considerable melaena for five days before admission to hospital on February 25, 1940. On admission he was pale and shocked, with blood pressure 90/50 and pulse rate 140. As his haemoglobin was 75%, it was decided to give him plasma; so between 12 noon and 5 p.m. on the 26th a litre of plasma was infused. The patient became confused and apathetic during the plasma administration, but consciousness was not lost. Following the plasma infusion there was no subjective improvement such as is normally brought about by blood transfusion in these cases. On the day after the infusion he felt better than he did immediately after, and blood-volume estimation showed that he had by that time lost the greater part of the increase in plasma volume brought about by the infusion. A barium meal on March 11 showed a chronic gastric ulcer with hour-glass deformity. The results of blood examination are as follows, and are shown also in Fig. 3.

Date and Time	Plasma Volume (litres)	Haematocrit %	Blood Volume (litres)	Blood Urea (mg. /100 c.cm.)	Plasma Protein (gm. /100 c.cm.)	Haemoglobin % (Haldane)	R.B.C. (millions)

Case 8: Bleeding from Duodenal Ulcer.—This patient, a man aged 56, had a seven-years history of dyspepsia, with occasional attacks of melaena. He had been passing dark stools for two days before his admission to hospital on February 26, 1940, and was very pale, with pulse rate of 100, blood pressure 90/45, and haemoglobin 56%. The next day he was given a litre of plasma over a period of three hours; there was a complete absence of improvement, and the pulse, which had been running at a level of 100, rose during the course of the infusion to 120, and remained at that level until the following day. The systolic blood pressure fluctuated between 90 and 120, and was 97 at the close of the infusion. Half an hour after beginning the infusion the patient complained of headache, but this was not severe. On March 4, since the haemoglobin was not rising, a blood transfusion was given, with definite improvement in the patient's subjective and objective condition, and he made a good recovery. A barium meal on March 12 showed deformity of the duodenal cap, although an ulcer crater was not actually demonstrated. The numerical values obtained are given below.

Case 9: Duodenal Ulcer.—After melaena for two days and one attack of haematemesis this patient, a man aged 47, was admitted to hospital on September 16, 1940. His blood pressure was 124/76 and pulse rate 90; he was pale but did not appear to be suffering from shock. A plasma infusion was started at 7 p.m. on the day of admission. There was no severe reaction, but headache began three hours after the infusion started, and lasted for over twenty-four hours. On the day after plasma infusion the pulse was 85 and blood pressure 122/64. He made a good recovery, and was discharged on October 14.

Summary

In nine patients with severe haemorrhage from the stomach or duodenum plasma compared unfavourably with whole blood in its effects on the blood volume and haemoglobin concentration. It did not lower the degree of azotaemia to the same extent as whole blood, and the general condition of the patients was adversely affected. It is suggested that the ill effects of plasma in these cases are due to forced dilution of the blood in excess of the limits within which blood dilution is favourable to recovery from haemorrhage. The circumstances which determine the usefulness of plasma in post-haemorrhagic shock are discussed: in general terms, plasma is contraindicated when the haemoglobin is less than 50%.

We are indebted to Prof. L. J. Witts for directing the research and for criticism of the paper.

AMPUTATIONS IN BED

BY

H. A. BRITTAIN, M.A., M.Ch., F.R.C.S.

Orthopaedic Surgeon, Norfolk and Norwich Hospital

Orthopaedic surgeons are proud, and justly so, of their aseptic operative technique. Consequently, when one of them advocates the performance of an operation in the patient's bed one can visualize the hackles rising. My apology and excuse is, "C'est la guerre," and the emergencies of war have forced us to modify the technique which in peacetime is rightly regarded as essential.

Air raids, the mechanization of the Army, and the intensified industrial output have caused a great increase in the numbers of injuries to the limbs. Motor-cycle accidents to dispatch riders have resulted in as many as sixty-one serious fractures in six months in one provincial hospital alone. These patients are often suffering from severe shock, and multiple injuries may be present. Prompt amputation of mangled limbs before adequate resuscitation is to be condemned. Nevertheless the patient may recover to a certain extent from the primary shock, and then his condition may degenerate into secondary shock as a result of extensive damage to the limb.

Indications for Amputation

The indications are: (1) severe compound fractures or crushed limbs that cannot survive owing to interference with the circulation; (2) infection by anaerobic organisms, with spreading gangrene; (3) laceration or crushing of soft parts to such an extent that (*a*) the presence of the limb is retarding recovery from or accentuating shock, or (*b*) the subsequent scarring will leave a useless limb.

Choice of the right moment to amputate is of paramount importance, and equally so is the execution of the operation with the least possible disturbance to the patient. Temporary suspension of continuous-drip transfusion, and transport to the theatre necessitating lifting the patient from the bed to the stretcher, from the stretcher to the theatre table, from the theatre table to the stretcher and back to bed again, often have a deleterious effect. There may also be difficulty in restarting the blood transfusion, which will certainly be necessary. Multiple injuries may render transport difficult or impossible. It may, of course, be possible to wheel the bed accompanied by the drip transfusion into the theatre, and in some hospitals, and in the absence of an overwhelming rush of casualties, this may be considered preferable. A mobile surgical team might have to perform an amputation in the patient's house. For these patients amputation in bed in the ward may be a life-saving measure, and it has been found that it can be quickly, smoothly, and expeditiously carried out if carefully planned beforehand and a formal technique is faithfully observed.

Technique

Essential Materials.—Samways' tourniquet, or Callandar's modification of same; large amputation knife; dissecting forceps; amputation saw; artery forceps; catgut or silk; sulphanilamide powder; vaselined gauze arranged as a dressing and laid on wool 8 in. by 8 in. and 1 in. thick; bandages; three strips of 2-in. strapping two feet long.

Anaesthesia.—Intravenous pentothal or cyclopropane. The former is to be preferred for ease of administration.

Assistants.—Three are required, apart from the anaesthetist, if available. Two is the minimum.

Operation.—Speed is desirable and often essential. An amputation through the lower third of the thigh is described, although the same technique can be adopted for any site. The guillotine operation is of course the method of choice in these severely shocked patients. The tourniquet is applied and kept in position by one assistant, who twists it round and holds it with his hands. Another assistant lifts the limb by the foot. Mackintoshes and towels are applied, and the incision is begun on the postero-medial aspect of the limb, continued over the front of the circumference of the limb, and carried down to the bone. The bone is quickly divided with a saw, the skin being pulled up as far as possible by pressure with the left hand. The femoral vessels are clamped and tied with silk or No. 2 catgut. An assistant then releases the tourniquet slightly, and any other strongly bleeding vessel is clamped and ligatured. The generalized ooze is ignored. The tourniquet is now held tight again, and sulphanilamide powder is dusted on to the raw area. Vaselined gauze and wool are then applied to the stump and firmly bandaged on. The dressing is further anchored in place by strapping, which passes over the end of the stump from the abdomen to the buttocks and from the inner to the outer aspect of the thigh. Below are given two illustrative cases.

Case I

A munition worker aged 18 became an air-raid casualty at 2 p.m. in August, 1940. The further history of his case is as follows:

3.15 p.m.—Admitted to hospital in fairly shocked condition. Blood pressure 120/80. Pulse 80, good volume. Talking clearly and well. Compound comminuted fracture of head of tibia. Morphine given and anti-shock treatment instituted.

4.15 p.m.—Plasma transfusion given preparatory to operation.

4.30 p.m.—Condition degenerating. Cold, perspiring, and cyanosed. Blood pressure 95/60. 6 litres of oxygen given with B.L.B. mask.

9 p.m.—Condition much worse. Blood pressure 85/50. Pulse rate risen from 100 to 160. Blood transfusion administered.

11 p.m.—Amputation through lower third of thigh performed in bed.

11.10 p.m.—Immediately after operation blood pressure 70/40.

Next day, 12.30 a.m.—Blood pressure 80/60. Pulse 140.

8.30 a.m.—Blood pressure 120/80. Pulse 120. Steady gradual improvement followed.

Case II

An R.A.F. dispatch rider aged 24 had a motor-cycle accident at 8.30 a.m. on November 15, 1940. His case proceeded as set out below.

November 15, 11.30 a.m.—Admitted to hospital with severe shock. Compound comminuted fracture of tibia and fibula plus fractured pelvis. Large wound with extensive laceration of soft parts. Pulse 100—irregular and of poor volume. Resuscitation started at once.

4 p.m.—Condition improved. Complete excision of wound, sulphanilamide pack, vaselined gauze, immobilization on Thomas splint with pins above and below fracture.

November 16.—Condition fairly good. Pulse still irregular —100 and poor volume.

November 17.—Definitely improving. Pulse still irregular. At 10.30 p.m., pulse 130. Wound examined. No local evidence of gas infection.

November 18. 3.30 a.m.—Pulse 120 Some crepitus in region of wound. Toes cold though not gangrenous. Plasma with 6 c.cm. of sulphapyridine and 20,000 units of polyvalent anti-gas-gangrene serum given.

6 a.m.—Asthmatic attack. (Patient subject to recurrent asthma.) Pulse 160. Oxygen given with B.L.B. mask. Adrenaline 80 minims given slowly and intramuscularly. Gross gas infection of leg present.

8 a.m.—Slight improvement in general condition, but gangrene spreading.

9 a.m.—Extensive gas gangrene below knee. Asthma controlled, but pulse still 130 and general condition very poor indeed. Blood transfusion given. Amputation through lower third of thigh in bed.

1.30 p.m.—Pulse 96. Condition improved. Steady gradual improvement from this stage.

All my colleagues and I feel certain that if either of these patients had been moved from his bed or from the ward his chances of recovery would have been seriously diminished.

Summary and Conclusions

It is suggested that the performance of amputations in the patient's bed, in the ward, the theatre, or his own house, may be the deciding factor in saving life, since the operation can be done with the least possible disturbance to the patient.

A simple technique for amputations in bed is described.

DOUBLE INFECTION OF THE MENINGES WITH MENINGOCOCCUS AND GAERTNER'S BACILLUS

BY

K. J. GUTHRIE, M.D.

AND

T. ANDERSON, M.B., F.R.C.P.Ed.

(From the Department of Pathology of the Royal Hospital for Sick Children, Glasgow, and Ruchill Fever Hospital)

The following case seems worth recording for two reasons—first, because it is extremely uncommon for a child to recover from one variety of meningeal infection only to fall a victim to another; secondly, because the type of meningitis which proved fatal is in itself comparatively rare. The primary infecting strain was meningococcus, the secondary *Bact. enteritidis* (Gaertner's bacillus).

Clinical Summary

A female infant aged 14 months was admitted to the Royal Hospital for Sick Children on June 16, 1940. She had been well until three weeks previously, when she became feverish, listless, and drowsy, began to refuse feeds, and vomited on several occasions. On June 15 the child had a convulsion. On admission to hospital she was flushed, with staring eyes, and had a marked "meningeal" cry. There was evidence of increased intracranial pressure, so lumbar puncture was performed. The fluid was under slightly increased pressure and was turbid: the cell count was 630 cells per c.mm., and films showed that these were both polymorphonuclear and lymphocytic. Meningococci were seen, mostly lying free, though a few were intracellular. On culture a heavy pure meningococcal growth was obtained. The child was transferred to Ruchill Fever Hospital on June 17. There the above findings were confirmed. Blood culture was negative. Treatment with sulphathiazole was instituted, and she received 20 c.cm. of sodium sulphathiazole intramuscularly and 0.75 gramme of sulphathiazole four-hourly by mouth. Lumbar puncture forty-eight hours after admission showed a clear fluid in which no meningococci were found in smears or on culture. She received 26.5 grammes of sulphathiazole in eight days, when the drug was stopped. The temperature settled within forty-eight hours of starting treatment, and progress was uneventful for almost a fortnight. On July 2, however, it was noticed that the patient was fretful and that the eyes were staring and wild-looking. There was occasional twitching of the eyes. Examination showed a paralysis of conjugate upward movement of the eyes and of conjugate movement to the right. The pupils were semi-dilated and did not react to light. An internal hydrocephalus was suspected. On July 8 there was a sudden rise of temperature to 107° F., and lumbar puncture was performed. Films showed abundant motile Gram-negative bacilli, and these were obtained in pure culture, the growth on MacConkey plates consisting of non-lactose-fermenting colonies. The child died twenty-four hours later. Necropsy showed fine adhesions between the pia and arachnoid, with considerable flattening of the convolutions. There was much inflammation of the surface of the brain, over which was a thin purulent exudate, mainly vertical. The ventricles were greatly dilated and contained thin purulent fluid.

Bacteriology

Cultures yielded a pure non-lactose-fermenting growth similar to that already obtained from the cerebrospinal fluid. Several colonies subcultured produced acid and gas in glucose, mannite, maltose, and dulcite, and failed to ferment lactose and saccharose. No indole was formed. A polyvalent Salmonella antiserum (Oxford standards) agglutinated cultures to titre. The strain was then tested against the various O (somatic) antisera of the Salmonella group, when agglutination occurred with *Bact. typhosum* O antiserum. This fact, taken in conjunction with the fermentation reactions, suggested that the strain was a member of the *enteritidis* group, which shares with *Bact. typhosum* the O antigens IX and XII. A further series of biological tests similar to that employed by Guthrie and Montgomery (1939), was next undertaken, the unknown Ruchill strain being tested in parallel with a known culture of *Bact. enteritidis* and of its closely related Dublin variant. The Ruchill culture behaved in every respect like the *Bact. enteritidis* strain. Confirmatory serological tests were then performed, when an antiserum prepared to the Ruchill strain agglutinated the homologous organism and several known *enteritidis* cultures to approximately the same high titre. Similarly a stock *enteritidis* antiserum agglutinated in high and approximately similar dilutions several known *enteritidis* strains and the Ruchill organism. Finally, the flagellar antigenic formula of the Ruchill culture was determined by the method of Kauffmann (1935–6). As already stated, it possessed the O (somatic) antigens IX and XII. Its H (flagellar) antigens were found by performing direct agglutination tests with antisera containing individual flagellar antibodies, employing the procedure described in detail by Guthrie and Montgomery. In common with various stock *enteritidis* cultures tested in parallel the Ruchill organism was found to possess the flagellar fractions g and m. Thus the serological, like the fermentative, reactions were those of a true *enteritidis* strain. The organism proved toxic for a rabbit, which succumbed within forty-eight hours of receiving an intravenous inoculation of 1/10 of a fresh agar culture suspended in saline. At necropsy the infecting strain was recovered in pure heavy growth from the heart blood, swollen spleen, and bile. The intestinal contents also were heavily infected.

Discussion

Few examples of double meningeal infection such as ours are to be found in the literature. A closely similar case is that reported by Opitz (1919) in a child of 15 months in whose cerebrospinal fluid meningococci alone were present originally. Subsequently Gram-negative bacilli appeared in films of the ventricular fluid, and a strain later identified as *Bact. enteritidis* was obtained on

culture. Welcker and Vogl (1938) also record a double infection of the meninges. Their patient, a female infant, was admitted to hospital with meningococcal meningitis, which improved under treatment; but a relapse occurred after a fortnight, when a Salmonella strain—in this instance *Bact. typhi murium*—was obtained in pure culture from the cerebrospinal fluid during life and at necropsy. Ravitch and Washington (1937), in the case of a 4-year-old girl, isolated meningococcus in pure culture from both the cerebrospinal fluid and the blood on the day of admission to hospital. A second blood culture taken twenty-four hours later gave a pure growth of *Bact. suipestifer* (the hog-cholera bacillus), and on the fourth day this organism alone grew from the cerebrospinal fluid. The authors considered, however, that as the spinal fluid was grossly contaminated with blood in the course of withdrawal the *suipestifer* strain may have been introduced in this way. Reid and Lipscomb (1940) saw streptococcal followed by pneumococcal infection after an interval of some months in a girl of 17. Both attacks of meningitis complicated mastoiditis.

A possible explanation of such double infections may lie in the fact that a primary inflammation of the meninges, by affecting the local capillaries and increasing the permeability of the endothelium, may predispose to a secondary meningeal infection. Burrows (1932) collected numerous instances of the localization of bacteria in injured or inflamed areas, which thus show lessened resistance.

Apart from its association with meningococcus, *Bact. enteritidis* as a cause of meningitis is of interest for its own sake, since organisms of the Salmonella group are among the rarer meningeal invaders. Comparatively few records of Salmonella meningitis are extant in the literature, and of these the great majority have appeared within the last decade. Most of the reports describe single examples, but series of collected cases are published by Lynch and Shelburne (1930), Bahrenburg and Ecker (1937), and Guerra *et al.* (1940). The last-mentioned authors' series is the largest, numbering 60 cases. Various Salmonella types have been incriminated—*Bact. paratyphosum* A (Eckert, 1910); *Bact. paratyphosum* B (Voigt, 1922; Brahdy, 1925; Anderson, 1932); *Bact. suipestifer* (Boycott and McNee, 1936; Clifton and Werner, 1938); *Bact. aertrycke* (Aballí *et al.*, 1937); *Bact. panama* (Katsampes and Bradford, 1940). Although these examples show that the Salmonella group as a whole possesses considerable powers of invasion, two members in particular are believed to have a special predilection for the meninges—*Bact. enteritidis* and *Bact. enteritidis* var. Dublin. Guthrie and Montgomery during a recent outbreak of *enteritidis* infection in young infants saw 10 cases with frank purulent meningitis due to this organism and 1 caused by the Dublin bacillus. They quote other examples.

The most striking fact concerning Salmonella meningitis which emerges both from our personal experience and from a survey of the literature is its marked tendency to affect infants—especially those in the neonatal period—rather than older children or adults. Nearly all the single case reports quoted concern babies under the age of 1 year, in whom meningitis was a sequel to Salmonella invasion of the blood stream, which occurs more readily in very early life than at any other age period. In fact, in young infants Salmonella infections tend to produce lesions quite distinct from those typically seen in adults. Similarly, young animals of various species are particularly susceptible to Salmonella infections (Hormaeche, quoted by Zerbino *et al.*, 1940), and septicaemia with purulent complications due to the Dublin bacillus has been described in young calves by Bosworth and Lovell (1931).

Infection apparently enters by way of the alimentary tract. Gross intestinal lesions do not, however, necessarily precede invasion of the blood stream. Sometimes, in fact, the gastro-intestinal tract appears normal, as in the present instance and in the cases of Symmers and Wilson (1908–9), Smith (1921), and Pesch (1926). Also Guerra *et al.* (1940), who with others have extensively investigated Salmonella infections in Uruguay within recent years, found evidence of enteritis only in the minority of their fatal cases. They suggest that, as in other meningeal infections, the portal of entry is pharyngeal, with subsequent invasion of the blood stream and localization in the meninges.

The origin of the *enteritidis* strain was not discovered in our case. As the organism was isolated from our patient for the first time three weeks after admission to hospital it was thought possible that she might have been infected from another patient. Specimens of faeces from all the other inmates of the ward were therefore examined, but all were negative. Inquiry elicited no history of diarrhoeal disease either in the child's family or in any member of the nursing staff before the onset of her illness. In infants contaminated cows' milk must be considered a likely source of Salmonella infection, particularly in the case of *Bact. enteritidis* and the Dublin bacillus, since these strains are among the commonest Salmonella invaders in cattle (Bosworth and Lovell, 1931), and at least two epidemics have been traced to infected milk (Kinloch, Smith, and Taylor, 1926; McAllan and Howie, 1931). In the present case the milk supply could be excluded as a source of infection, since it was a bulked certified milk and was supplied to a large number of infants without mishap. The source of sporadic Salmonella infections often remains obscure, and difficulty in incriminating milk or some other article of food as a vehicle of infection may depend partly at least on the varying resistance of those consuming it, since even a small inoculum may produce disease in subjects so peculiarly susceptible as young infants, while a much larger dose may be borne with impunity by older individuals.

Summary

A case of double meningeal infection in a child is reported and the bacteriology of the condition is discussed.

The literature is given of the few other cases that have been placed on record.

We are indebted to Dr. W. M. Elliott, medical superintendent, Ruchill Hospital, for permission to use the case record.

A COMPARISON OF RESULTS OF SURGERY AND RADIOTHERAPY IN CARCINOMA OF THE CERVIX UTERI

BY

W. R. WINTERTON, M.B., B.Ch., F.R.C.S., M.R.C.O.G.

Assistant Gynaecological Surgeon to the Middlesex Hospital and Soho Hospital for Women

AND

B. W. WINDEYER, M.B., B.S., F.R.C.S.Ed., F.F.R., D.M.R.E.

Medical Officer in Charge, Meyerstein Institute of Radiotherapy, the Middlesex Hospital

This series of 179 cases of carcinoma of the cervix shows the five-year results obtained in all patients suffering from this disease who were seen at the Middlesex Hospital during the years 1931–4 and who had received no previous treatment. They afford material for comparing the various methods of treatment adopted. These patients have been treated surgically by several members of the surgical staff, and by radiotherapy by the radiotherapy staff of the Meyerstein Institute of the Middlesex Hospital. We are indebted to them for permission to study and report their results.

The importance of the series is that it gives the results obtained from the total number of cases of carcinoma of the cervix undergoing treatment at a single hospital when both surgical and radiotherapeutic methods have been available. Each patient was seen in the first instance by a surgeon with a view to the performance of Wertheim's hysterectomy, and only those cases which were inoperable by reason of the extent of the growth, of age, or of general condition were referred for radiotherapy. In two cases radiotherapy was given because operation was refused. Sixty-four were treated by surgery, 104 by radiotherapy, and 11 received no treatment.

The surgical cases consisted of 59 patients treated by surgery alone and 5 to whom post-operative *x*-radiation was given in addition. The radiotherapy cases were made up of 87 patients treated by a combination of radium and *x* rays, 14 treated by radium alone, and 3 treated by *x* rays alone. The 11 cases untreated consisted of 1 patient who refused treatment and 10 who, either on account of widespread dissemination of the growth or because of their hopeless general condition, were considered to be too advanced even for palliative measures.

The surgical operability rate was 64 out of 179 cases—i.e., 35.7%. The radiotherapy treatment rate was 104 out of 115 cases—i.e., 90.4%. Eleven cases (6.1%) were untreated. The average age of the patients was 53.5 years, the youngest being 31 and the oldest 80. There were 9 nulliparous women in the series (5%), and one of these was clinically a virgin. Histological confirmation of the diagnosis was obtained in 159 out of the total of 179 cases, but such confirmation was obtained in every patient but one of those who survived five years. There were 152 cases of squamous-celled carcinoma and 7 of adenocarcinoma. All the patients treated have been kept under continuous observation for more than five years, with the exception of two who could not be traced.

Classification of Cases

The series of patients treated by radiotherapy has been divided into the four stages of the League of Nations classification, which is as follows:

Stage 1.—The growth is strictly limited to the *cervix uteri*. Uterus mobile.

Stage 2.—Lesion spreading into one or more fornices with or without infiltration of the parametrium adjacent to the uterus, the uterus retaining some degree of mobility.

Stage 3.—(*a*) Nodular infiltration of the parametria on one or both sides extending to the wall of the pelvis, with limited mobility of the uterus or massive infiltration of one parametrium with fixation of the uterus. (*b*) More or less superficial infiltration of a large part of the vagina with a mobile uterus. (*c*) Isolated metastases in the pelvic glands, with a relatively small primary growth. (*d*) Isolated metastases in the lower part of the vagina. [Generally speaking, all cases not falling into Stage 2 or 4 will be placed under Stage 3.]

Stage 4.—(*a*) Cases with massive infiltration of both parametria extending to the walls of the pelvis. (*b*) Carcinoma involving the bladder or rectum. (*c*) The whole vagina infiltrated (rigid vaginal passage), or one vaginal wall infiltrated along its whole length with fixation of the primary growth. (*d*) Remote metastases.

The League of Nations classification has not been used for the surgical series, which has been divided into two groups according to the results of histological examination of the glands removed at operation: (1) glands free from carcinoma: (2) glands invaded by carcinoma. It was often found at operation that patients clinically belonging to Stages 1 and 2 of the League of Nations classification had invasion of the glands and, conversely, that patients having extensive local growth had no invasion of the glands.

Results

Results have been assessed in terms of five-year survival rather than of cure. This has been done in order to avoid any difficulty in the interpretation of the significance of residual pelvic thickening following treatment. In fact, all the 26 survivors in the radiotherapy group remained free from signs or symptoms of disease during the five years following the completion of their single course of treatment. During the sixth year one patient developed lumbar pain without definite evidence of recurrence. She received a course of *x*-ray treatment, and now remains well, two years later. Of the 23 patients who survived five years following surgical treatment 2 had signs of recurrence of the growth during the fifth year and have since died.

TABLE I.—*Wertheim's Hysterectomy*

	No. Treated	Died of Operation	Died of: Cancer	Died of: Other Causes	Untraced	Five-year Survival
Glands not invaded	46	6	16	3	2	19 (41.3%)
Glands invaded ..	18	5	8	1	0	4 (22.2%)
Total	64	11 (17.2%)	24	4	2	23 (36%)

Five of the patients in Table I were given post-operative *x*-ray treatment. We can find no indication for the selection of these patients, as 3 had no glandular involvement and in 2 the glands were involved. They all died before the end of the five-year period.

TABLE II.—*Radiotherapy*

	No. Treated	Treatment Mortality	Died of: Cancer	Died of: Other Causes	Untraced	Five-year Survival	
Stage 1	12	0	5	0	0	7 (58.3%)	44.4% / 35.3%
,, 2	13	1	7	1	0	4 (31%)	
,, 3	43	2	27	1	0	13 (30%)	
,, 4	36	2	32	0	0	2 (5.5%)	
Total	104	5 (4.8%)	71	2	0	26 (25%)	

The routine method of radiotherapy used has been the combination of the insertion of radium to the uterus and vagina by the Paris technique, and the application of *x* rays to the parametria. Eighty-seven patients were treated by this method. Before the adoption of this routine 14 cases were treated by radium alone. At this time a modification of the Stockholm technique was employed. Only one of these patients survived the five-year period. Three were treated by *x* rays alone as a palliative measure because their condition was so bad that radium could not be applied. Two of them died during the course of treatment, and the third shortly after it had finished.

Combined Results of Surgery and Radiotherapy.—Out of the 179 who applied for treatment 49 survived five years—i.e., an absolute survival rate of 27%. If from the 179 patients deductions are made of those untreated (11), those untraced (2), and those who died of other causes while free from disease (6), the relative survival rate is 49 out of 160 cases—i.e., 30.6%.

Discussion

With the two methods of classification employed it is difficult to compare accurately the results obtained by surgery with those obtained by radiotherapy, but such comparison is still of value. Even though cases treated by radiotherapy which are clinically Stages 1 and 2 may have glandular invasion, a comparison of these groups with the surgical gland-free cases shows 44% five-year survivals treated by radiotherapy as against 41.3% of the surgical cases.

The surgical cases with glands may be compared with the Stage 3 (*c*) radiotherapy cases—i.e., "isolated metastases in the pelvic glands with a relatively small primary growth." Almost all the remainder of the Stage 3 radiotherapy cases must be regarded as inoperable, as can be seen from the relatively large number considered unsuitable for surgery and referred for radiotherapy. Nevertheless, comparison of the results of all the Stage 3 radiotherapy cases of every category with the "gland-invaded" surgical cases shows 30% of five-year survivals from radiotherapy and 22.2% of five-year survivals from surgery.

If the cases in Stages 1, 2, and 3 treated by radiotherapy are compared with all the surgical cases, both "gland-free" and "gland-invaded," then the figures show 35.3% five-year survivals from radiotherapy and 36% of five-year survivals from surgery—an approximately equal figure; but there were 63% of Stage 3 cases in the radiotherapy figures and only 28% in the surgical figures.

These results were obtained with an operative mortality of 17.2% in the patients treated by surgery and with a treatment mortality of 4.4% in the patients receiving radiotherapy. In this series, moreover, consideration must be given to the fact that the results of radiotherapy were obtained in patients who had previously been rejected by a surgeon as unsuitable for surgery either on account of extent of growth or of poor general condition. The material for radiotherapy was therefore much inferior to that treated surgically, and allowance must be made for this in any comparison of these two methods of treatment based on this series.

Conclusions

In technically operable cases of carcinoma of the cervix a higher percentage of five-year survivals has been produced by radiotherapy than by surgery.

This result has been obtained with a much lower treatment mortality.

In technically inoperable cases of carcinoma of the cervix a small percentage of five-year survivals has been obtained by radiotherapy.

Clinical Memoranda

Friedländer Pneumonia successfully treated with Sulphapyridine

The following case is an example of a rare type of acute lobar pneumonia which is not widely recognized in this country and is therefore probably often overlooked. Its signs and symptoms have been well described in two series of cases in America (Bullowa *et al.*, 1937; Solomon, 1937), and there can be no doubt that it is a distinct clinical entity. It is characterized by profuse slimy brightly blood-stained sputum containing a pure culture of Friedländer's pneumobacillus, pronounced toxaemia, and a very high mortality (83% in the first series mentioned and 97% in the second). If the patients survive long enough septic complications such as lung abscess or empyema usually develop.

Case History

The patient, a man aged 43, was admitted to the Western General Hospital, Edinburgh, in March, 1939. He had been ill for five days with a cough, and during the past three days had been bringing up large quantities of slimy sputum which was heavily blood-stained. On examination he was very collapsed. There were typical signs of consolidation of the right lower lobe; this was confirmed by radiograph. His temperature was 100° F., and the white blood count was 8,000 per c.mm. His sputum, which was quite unlike the usual rusty sputum seen in acute lobar pneumonia, contained many Friedländer pneumobacilli but no other organisms. Blood culture was negative, and remained so.

He was immediately given four 0.5-gramme tablets of sulphapyridine, and four more two hours later, and then two tablets four-hourly. His temperature fell to normal in forty-eight hours, with marked clinical improvement, but rose again after a further twenty-four hours, and two days later he developed a right-sided empyema. The pus contained a pure growth of Friedländer's pneumobacillus. He was treated by rib resection and drainage, and made an uninterrupted recovery. Sulphapyridine was stopped six days after admission, a total dosage of 32 grammes having been given.

Discussion

In a disease with such a mortality the mere survival of a patient following use of sulphapyridine suggests that the drug is potent against the bacillus. This was supported by the rapid clinical improvement in the early stages of treatment. The development of an empyema does not indicate that the drug was without value, as such a development is common in acute pneumococcal lobar pneumonia, in which the value of the drug is of course undoubted.

I have been unable to trace any other detailed report of treatment of a similar case, but Long and Bliss (1939) have had good results in experimental infections in mice, and they recommend the use of the drug in any Friedländer infection in man. Meyer and Antman (1939) report the successful treatment of a case of septicaemia due to the bacillus, the source of infection being unknown.

It is obviously impossible to generalize from one case, but it is hoped that mention of it may help to draw attention to the existence of this interesting condition and to the possibility of its successful treatment.

My thanks are due to Prof. Stanley Davidson for permission to publish this case.

FRASER SINCLAIR, M.D.
Surg. Lieutenant, R.N.V.R.

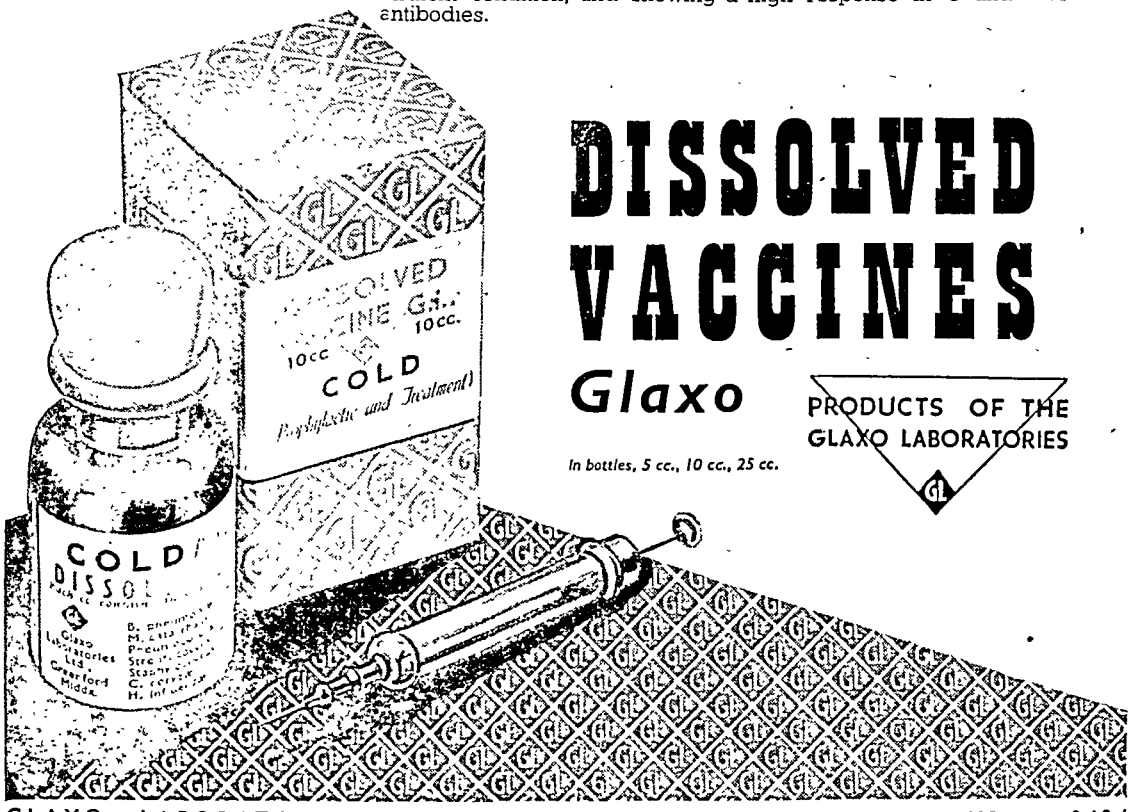
Swift antibody response



without disabling reaction

in effect a new Immunotherapy

The Common Cold The principles of immunotherapy established by Dissolved Vaccines *Glaxo* give the physician a degree of control over the common cold which, in the large majority of cases, is decisive. The normal prophylactic course, if given now, is usually enough to secure immunity for a period often lasting throughout the remainder of the season. A knowledge of the patient's susceptibility (which of necessity must influence the *period* of immunity) is of value in helping to decide if and when a refresher course should be given, The initial course is three injections (0.5 cc., 1 cc., and 1 cc.) given at weekly intervals. If a cold is already in the "threatening" stage, it can often be aborted by a dose of 0.5 cc., followed by 1 cc. the next day.

Whooping-cough Inoculation with Whooping-cough Dissolved Vaccine *Glaxo* enables a large proportion of contacts to escape the disease entirely. In treatment, attacks are rendered mild and brief, and not infrequently are completely aborted. The effectiveness of Whooping-cough Dissolved Vaccine depends on the fact that the total antigens are available immediately on injection, thus securing a rapid antibody response. Furthermore, because the vaccine is detoxicated, it is possible to give full dosage from the beginning, even to young children painlessly and without undesirable reactions. The effective scheme of dosage is 3 or 4 injections, beginning with 0.25 to 0.5 cc., (according to age) and rising to 1 cc.

Typhoid Satisfactory immunisation, without undue pain or systemic reaction, is secured with 2 injections of Anti-typhoid Paratyphoid Dissolved Vaccine *Glaxo*. The dosage is 0.5 cc., followed by 1 cc., seven to ten days later. The Vaccine is prepared from strains maintained in a highly virulent condition, and showing a high response in O and "Vi" antibodies.

Reviews

POSTGRADUATE LECTURES IN MEDICINE

Edinburgh Post-Graduate Lectures in Medicine. Volume I. 1938–9. By Various Authors. (Pp. 513. 10s. 6d. net.) Edinburgh and London: Published for the Honyman Gillespie Trust by Oliver and Boyd. 1940.

The high standard of clinical teaching has earned the Edinburgh School of Medicine a great reputation in the past. Since 1906 the growing need for postgraduate instruction has been met by holding vacation courses, and such three-weeks courses arranged for general practitioners have been highly successful and well attended. For two years before the war a more prolonged period of postgraduate training had been arranged and full numbers of entries were obtained. It is likely that further facilities will be needed and offered. Towards the cost of this a grant has been made by the Honyman Gillespie Trustees and a first series of lectures is published in a convenient volume, being reprinted from the *Edinburgh Medical Journal*. It is prefaced by a summary of the aims and attainments of the Postgraduate Executive Committee by its chairman, Dr. Edwin Bramwell, whose subsequent lecture on the pupil reactions is a model of clarity with a proud account of the contributions of alumni of the Edinburgh school to knowledge of the subject. Robert Whytt described the reactions of the pupil to light and the consensual reaction; T. R. Fraser discovered the myotic action of physostigmin; Douglas Argyll Robertson is specially remembered in relation to the pupillary sign which bears his name; while recently S. A. Kinnier Wilson and W. J. Adie have in their writings thrown further light on pupil problems. Other lectures on the nervous system deal with the visual path and its interruptions by disease, and with other problems of neurology, especially the syndromes of deficiency disease, and recent work on myasthenia and myotonia.

Specialists have contributed to bring together an admirable survey of recent advances and attainments in medicine, including circulatory problems by Prof. Ritchie and Dr. Rae Gilchrist, chest complaints by Dr. Fergus Hewat, Prof. Christie, and Prof. McNeil, renal disease by Prof. Lyon and Dr. Cameron, and hepatitis by Prof. McNee. A wide range of surgical subjects includes consideration of malignant disease of the colon by the late Sir David Wilkie and of the acute abdomen in children by Dr. Gertrude Herzfeld, while Prof. Illingworth gives an account of recent developments in the surgery of obstructive jaundice and the factors concerned in the causation and control of haemorrhage during and after operation. Prothrombin deficiency, which is the basis of the diminished clotting power of the blood, is found in two distinct conditions—jaundice and biliary fistula—suggesting that the deficiency may be due to faulty absorption of some substance from the intestinal tract owing to the lack of bile; favourable reports have been submitted on the value of intramuscular injection of vitamin K. Other surgical problems dealt with are cancer of the breast, toxic goitre, cancer of mouth and jaws, the results of ureteral transplantation, and the treatment of haemorrhoids.

Other subjects of general interest are the development of physical education and assessment of capacity for exercise and even some vocational guidance attained in the last ten years by the new Department of Physical Education; the advantages of occupational therapy among convalescent and chronic patients and the feeble-minded; and especially a sound and wise consideration of the use of intelligent psychotherapy in general practice by Dr. T. A. Ross. The volume is a good addition to the practitioner's library.

DENTAL ANAESTHESIA

Essentials of General Anaesthesia: With Special Reference to Dentistry. By R. R. Macintosh, M.A., M.D., F.R.C.S., D.A., and Freda B. Pratt, M.D., D.A. (Pp. 324. 25s. net.) Oxford: Blackwell Scientific Publications Ltd. 1940.

Any book written by the Nuffield Professor of Anaesthetics and his first assistant would compel attention, and this one certainly deserves it. In order to avoid disappointment the subtitle of this volume should be remembered, and it will then be realized that it is not meant to be a textbook on anaesthetics as a whole. The groundwork of the subject is covered, but detailed techniques are given for dental anaesthesia only. A short historical summary is followed by an excellent and up-to-date account of the theory and signs of general anaesthesia. Premedication and full details of every method applicable to dental surgery are discussed, the chapter on endotracheal anaesthesia being a particularly good one. Difficulties and emergencies are dealt with in a more practical manner than is often the case. The chapter on general analgesia is long overdue in a textbook published in this country. The conservative attitude of the medical profession to this subject is illustrated by a recent correspondent to a leading medical journal who denied that such a condition existed.

Some of the views expressed in this book would not be endorsed by the majority of anaesthetists. An example of this occurs in the chapter on "status lymphaticus," in which the work of such authorities as Sir Bernard Spilsbury in this country and E. H. Campbell and W. N. Kemp in America seems to have been disregarded. As a whole, however, the theoretical parts are sound, sane, and well balanced. A minor criticism of a style which is usually meticulously accurate is the use of the term "local anaesthesia" for "local analgesia." American influence is apparent throughout, but it is not carried to excess, and the real advances which have been made in the New World have been judiciously used. The printing is excellent and the illustrations deserve special praise. Most of them are original and many are in colour, a method that is particularly effective in dealing with such subjects as cyanosis and tissue oxidation.

This book should prove most useful to students for supplementing routine lectures on the principles of anaesthesia, and also to all who wish to perfect themselves in the techniques of dental anaesthesia.

SPECIALTIES IN MEDICAL PRACTICE

Specialties in Medical Practice. Edited by Edgar van Nuys Allen, M.D. With a foreword by Donald C. Balfour, M.D., F.A.C.S., F.R.C.S., F.R.A.C.S. Volumes I and II. (Pp. 934; 300 illustrations.) New York and Edinburgh: Thomas Nelson and Sons.

These two volumes on the specialties in medical practice, which are issued as a supplement to the Nelson series of loose-leaf publications on systematic medicine, will appeal to the medical man who wishes to supplement his courses of postgraduate study or to bring his knowledge up to date; the specialist may find the matter too superficially treated. They will also be welcomed by the general practitioner, for nearly one-half of the contents are

devoted to simple conditions of the eye, ear, nose, and throat, their diagnosis and treatment; to fairly detailed instructions on the management of pregnancy, antepartum, labour, and the puerperium; to the diagnosis and operative or other treatment of gynaecological conditions; and to the examination of urological and proctological cases.

But they will appeal especially to the practitioner who cannot easily call in the help of, or refer his patients for treatment to, specialists. For example, the treatment of haemorrhoids is described in detail from simple cleansing and supporting measures to the technique of injections and of amputation and plastic operations. In a chapter of about 100 pages Dr. W. O. Thompson covers all the essential knowledge of endocrinology. Most of the syndromes associated with affections of the various glands of internal secretion are dealt with adequately, and though the dietetic management of obesity and diabetes mellitus can only be sketched in, it is remarkable how much useful information the contributor has brought together. There is a good summary by Dr. D. L. Wilbur of available knowledge of vitamins and vitamin deficiency diseases, while the discussion of the phenomena of allergy by Dr. Frank A. Simon is of practical value to those who are called upon almost daily to treat bronchial asthma, urticaria, hay fever, and allergic forms of eczema. A short and practical note on management of common joint and bone lesions is contributed by Dr. Don King. The review of neurology by Dr. Henry R. Viets is well written and useful for reference, and includes a helpful discussion of methods of treatment. The section on extrapyramidal lesions is especially good.

There is some disproportion in the space devoted to certain diseases. For example, the article on disseminated sclerosis is very short, not much more than half a page, while that on rabies is more than twice as long. Tabes dorsalis is not considered except in differentiation from peripheral neuritis, while general paresis is dealt with in the section on psychiatry. In different countries the incidence and importance of diseases vary, and this work is written for practice in the United States. The loose-leaf system allows new sections to be added or old ones to be replaced without interfering with the book as a whole. A further section on venereal diseases is projected.

BONE AND JOINT INJURIES

Fractures and Other Bone and Joint Injuries. By R. Watson-Jones, B.Sc., M.Ch.Orth., F.R.C.S. Second edition. (Pp. 724; illustrated. 50s., plus 1s. postage.) Edinburgh: E. and S. Livingstone. 1941.

That a second edition of this large and expensive volume should be required within one year is a high compliment to the author, and is amply merited. A fresh perusal confirms the very high opinion which we formed of its value when it first appeared, and it will certainly become an English classic on the treatment of fractures. The chief alteration in the second edition is the chapter on war wounds, which has been entirely rewritten, and as this includes a full discussion of the treatment of open and infected fractures and the closed plaster technique its value at the present time will be obvious. That it should be possible to obtain perfect functional results, in the grave injuries described and illustrated, by so simple a method as a closed plaster must be wellnigh incredible to a surgeon brought up in the elaborate antiseptic methods current in the last war. There can, however, be no question as to the soundness of the method, provided that it is properly carried out, and the excellence of the results obtained.

Notes on Books

Few users of microscopes know all that they should about them, from the medical student who often does not even understand how to keep them in order to the microbiologist who perhaps uses apochromatic objectives without really understanding their construction. These deficiencies in knowledge, whether of elementary technique or of the science of optics as applied to microscopy, can be made good by reading *The Microscope*, by R. M. ALLEN (Chapman and Hall, 15s.), a work which is technical enough to be useful and yet simple enough to be intelligible. The main chapters on the structure and use of the microscope are preceded by a short account of its historical development, and followed by a long chapter on the preparation of material for microscopical examination, the methods described including those employed not only in histology and microbiology but in entomology, petrography, and metallurgy. Each of these and the subject of photomicrography are too briefly dealt with for the account of them to serve alone as a practical guide. There is little to criticize in the main part of the book, but room might be found for an account of the construction of the modern binocular tube, for instructions on how to find out whether a condenser is out of centre, and perhaps for a "fault-finding table" as supplied for motor cars. The illustrations mostly depict instruments of American or German manufacture, and the author deplores the failure of English makers to introduce their products in the U.S.A., since "some of their designs are very appealing to discriminating microscopists." We on our side of the Atlantic may well hope that British firms will make the best possible use of present opportunities.

A Guide to Human Parasitology for Medical Practitioners, by Prof. D. B. BLACKLOCK and Dr. T. SOUTHWELL, appeared originally in 1931 and has already reached a fourth edition (H. K. Lewis and Co., 12s. 6d.). Parasitology in the sense in which the word is used by the present authors includes the spirochaetes (but not the bacteria), also protozoa, platyhelminths (tapeworms and flukes), and nematodes. There is also a short section on myiasis, and this is perhaps the least satisfactory part of the book. The work also contains much general matter, such as an introduction to the use of the microscope, notes on the study of material, etc., and also much tabulated fact on the geographical distribution of worms parasitic in man, or those that are spread by water, by meat, and by various other channels. The reader may perhaps feel that the book is rather disjointed and that it is a series of condensed notes rather than a continuous whole, but it is admirably clear and brief and well illustrated, though one could wish that the magnification of the figures were more frequently given. The book is widely used not only by those who require a formal knowledge of tropical medicine and public health but by many practitioners and laboratory workers in all warm parts of the world.

The design of the little book *A Course in Practical Biochemistry for Students of Medicine*, by A. T. CAMERON and FRANK D. WHITE, is such that it offers greatest value when used in conjunction with the senior author's well-known and popular *Textbook of Biochemistry*, but the rapidity with which new editions have been called for tells of its own success. Some of this is due to the fact that it does not fall into an error commonly made by authors—that of loading elementary students with an embarrassing amount of detail. This volume (fourth edition, J. and A. Churchill, 9s. 6d.) aims at simplification, and excludes all but the essentials. Occasionally the process is overdone, with the result that instructions in some places seem a little bare. The authors rely mainly on well-tried and long-established methods, though where recent work has provided clearly improved forms of test they have not hesitated to adopt them. Thus, for example, in regard to carbohydrates we find the diphenylamine test for fructose, the Sumner-Bial reaction for pentose, and the diazo-uracil test for sucrose—all of fairly recent origin. For so important a practical exercise the blood urea determination receives less space than it deserves, and, moreover, as the method stands it falls technically below the best that could be recommended for teaching to students.

LICE AND DISEASE

Both varieties of the human louse, *Pediculus humanus*, were found in England before this war, but whereas the body louse, *Pediculus humanus corporis*, was seen comparatively rarely, the head louse, *Pediculus humanus capitis*, was much more common. The body louse was usually considered to be restricted almost entirely to vagrants, and although occasionally as much as 5% of a draft of Army recruits has shown signs of infestation, among the general mass of recruits and hospital patients well under 1% have had any body vermin. The head louse, on the other hand, was always exceedingly common. In a recent extensive survey on behalf of the Board of Education and the Ministry of Health Mr. Kenneth Mellanby[1] has shown that in our industrial cities nearly 50% of the girls and 30% of the boys—at least in the poorer sections of the community—had verminous heads during the year immediately before war was declared. The majority of these children had some live lice in their hair and not merely a few nits. In rural districts the situation was much more satisfactory, and it was rare to find more than 5% of any group of country children with head lice, although there is evidence that thirty years ago rural children were as frequently verminous as urban children are to-day. The crab louse, *Phthirius pubis* (often called *Pediculus pubis*), is in peacetime probably about as common as the body louse. Infestation is usually, but by no means always, venereal, and so crab lice may be expected to increase somewhat in wartime. There is probably much less danger of a general infestation throughout the population with *Phthirius* as compared with *Pediculus*, but the possible importance of the crab louse should not be entirely overlooked. The small peacetime reservoir of body lice and the widespread population of head lice might, under conditions favourable to the insects, give rise to practically universal infestation. Unless effective precautions are taken during the war, when so many people are living in shelters and are often unable to change their clothes, and when washing and laundry facilities are among those most easily disorganized, conditions may arise which will be ideal for the louse to increase and multiply.

The life history of both varieties of *Pediculus humanus* is similar: the female lays up to ten eggs a day; these may hatch within ten days, and after a further period of ten days the adults appear. If lice or their eggs are kept away from the body during part of the day their metabolism is reduced and the period of the life history greatly prolonged. At no stage can a louse live more than a month away from man, who is the insect's only source of food. Prof. Buxton[2 3] has shown that if breeding is not checked a single female might produce 120 daughters and 14,400 granddaughters, and within a short time a small louse population may increase to alarming proportions. The body louse is normally kept in check, except among the few vagrants who are chronically infested, by such simple measures as removing the day clothes at night (this alone will halve the rate of breeding) and by changing underwear, which removes the bulk of both eggs and other stages of the insect. If these things are done regularly, even in the face of frequent reinfestation, the parasites are unlikely to establish themselves on a new host. With the head louse most infestations are fairly light, and the ordinary combing of the hair, though ineffective in exterminating the parasite, serves to keep the population down to fairly small numbers; but if this combing were neglected, even for only a few days, these lightly infested heads would soon bear enormous populations and spread the infestation rapidly elsewhere.

If lice increased greatly their presence and the irritation of their bites would cause a great deal of discomfort, and it is probable that the inability to keep free from parasites might have a dangerous effect on the morale of large sections of the population. The possibility, however, of the appearance of louse-borne disease is of even greater importance. Typhus was formerly not uncommon in England, and if it were reintroduced at a time when lice were common (and transmission by both head and body lice is possible) a disastrous epidemic might occur. It is true that during the last war typhus never established itself on the Western Front, and some workers consider that for this reason it is unlikely to reappear in England, but the risk is one that cannot be ignored. With troops returning from areas where typhus is endemic, the introduction of the disease into England might be difficult to prevent. It must also be remembered that typhus is one of the few diseases that could be introduced by enemy action, for infected lice or infected louse faeces could be spread over our cities from aeroplanes, and the insects would easily survive even if dropped from very great heights. Relapsing fever, transmitted by lice, is also endemic in Eastern Europe, and this disease might similarly be introduced into England. As trench fever disappeared almost immediately after the last war its causation is imperfectly understood, but it is certainly transmitted by lice, and if the insects became common it might well reappear, this time among the civilian population.

If peacetime standards of cleanliness and hygiene can be maintained, then the louse menace will be avoided. It will be necessary to provide abundant facilities for hot baths and obtaining clean underwear for those whose homes have been damaged or where the public utility services have been put out of action. All cities should have ample supplementary disinfestation premises available in case of air-raid damage to the usual centre or in case there is a sudden increase in the number of parasites, for it is the disinfestation centre that should deal with the very verminous individuals who form the reservoir of body lice. Any measures taken at once to prevent an increase in infestation will be much more effective than those which will become necessary if we wait until the louse population has got out of hand. As well as the simple hygienic measures suggested above, recent research has

[2] *The Louse.* By P. A. Buxton. London, Arnold, 1939.
[3] *British Medical Journal*, 1940, 2, 603.

shown that certain insecticidal powders whose formulae are not yet published may be effective in checking infestation for many days after a single application of the powder to the underclothing.[3] If this work could be put into practice a great advance would be made, and an added protection would be available to those temporarily unable to live under civilized hygienic conditions. But our ideal must always be that such measures, useful as an added protection, should never be considered as the main defence against lousiness.

With regard to the head louse, although this parasite is most common in children, adults are by no means immune, for Mr. Mellanby finds[1] that even in pre-war conditions as much as 10% of adult women may be infested, sometimes very heavily. Even under war conditions these women could keep their heads free from vermin by thorough combing, particularly if this were done by using a specially made fine steel comb; suitable publicity on these lines should prove effective in preventing much increase. Use can also be made of the various liquids available which will easily kill all head lice and their nits; 70% alcohol (made from methylated or rectified spirit and applied so that the hair is kept wet for about an hour) appears quite efficacious and is perhaps the simplest.[2,3] It seems not unlikely that the war will greatly reduce the incidence of head lice among children who are evacuated to rural areas. Here they will learn to conform to a new standard of cleanliness by living among people who have come to know that the head louse may be easily dealt with by themselves in the home and who do not therefore feel dependent on a highly organized service provided by the State to deal (as it happens, not very effectively) with such problems. It must be realized that, in the case of both head and body lice, if the people likely to be infested can be made to co-operate in combating possible infestation, then the problem will be far on its way towards solution.

If total extermination is impracticable, it is obviously important that the louse should be kept in check in order to prevent a widespread degree of discomfort, which may be a danger to morale, and to avoid the possibility of louse-borne disease. So far as the body louse is concerned this can be attained by the maintenance of peacetime standards of hygiene. The war may even be made the opportunity for improving the situation by making the nation conscious of the deplorable hygienic standards which allow the degree of infestation by the head louse found even in peacetime.

CARCINOGENS IN THE LIVER

Are cancer-producing substances commonly present in the body under ordinary conditions? This is now one of the problems of Medicine. A few substances of proved carcinogenic power—tar and certain lubricating oils, for example—are met with in industry, but these account for only a small proportion of the cancers which appear in man. How are the great majority caused?—by naturally occurring carcinogens, hormonal or other? Chemists have produced large numbers of new carcinogens for research purposes, but of these not one is known to occur in the body under ordinary conditions. At first methylcholanthrene aroused special interest, for here at last was a carcinogen which might conceivably be formed in the body by simple chemical transformation of deoxycholic acid, a normal constituent of bile. As yet, however, there is no evidence that such *intra vitam* transformation does in fact take place. Some few common substances—as, for example, sugar in rats and lard in fowls and mice—may on rare occasions give rise to tumours at the site of inoculation, but of all the potent carcinogens hitherto found only the ovarian hormone is ordinarily present in the body. Painted on the skin of mice or injected subcutaneously, oestrone readily produces mammary tumours, the actual incidence depending on the strain of mouse. There is evidence, too, that ovarian hormones do, sometimes at least, play a part in the causation of naturally occurring mammary carcinomas in women.

Are there still unknown carcinogens to be discovered in the body? For the past five years Prof. Shabad of Leningrad has been working on this problem. In earlier papers he claimed that bile from cancerous human subjects contains a carcinogen which is demonstrable by experimental means. Now Kleinenberg, Neufach, and Shabad[4] report that tumours can be induced in mice by repeated injections of benzene extracts of human liver. Extracts from non-cancerous subjects are definitely active, and extracts from cancerous subjects show considerably greater activity. The resulting tumours in mice are of many different kinds, and include benign and malignant tumours of connective tissue, mammary glands, skin, sebaceous glands, maxillae, stomach, and liver. The type of the tumour which affected the human subject from whom the liver was taken had no effect on the type of tumour produced in mice. Moreover, most of the mouse tumours appeared in parts of the body remote from the site of inoculation.

If we accept the findings of Shabad at their face value we must conclude that pervading the human system there is something which when present in excess becomes manifest in a liability to neoplastic disease, and we must conclude, too, that this liability is to all kinds of neoplastic disease and not simply to one histological type alone. The results obtained in the principal experiment appear to be significant, though the number of reacting animals is small; for if we consider only mice surviving eight months or more, which seems fair, and exclude all benign tumours, which seems a little hard, we find 2.3% malignant tumours (all kinds) in the controls, 5.5% in mice receiving extracts from livers of non-cancerous subjects, and 22.2% in mice receiving extracts from livers of cancerous subjects, the actual figures being 9, 3, and 24 cancerous mice respectively. The effective substance seems unlikely to have been produced during the extractions, as excessive heating was always avoided. In any case the extracts of livers from non-cancerous subjects formed valid controls. And yet on general grounds one hesitates to accept the evidence. If a carcinogen of entirely general properties were really present in the body to the extent and with the frequency suggested by the experiments, and if it were really responsible for the majority of human cancers, then it might perhaps be expected that multiple primary

[4] *Amer. J. Cancer*, 1940, 39, 463.

tumours, or even completely generalized primary conditions, would be more prevalent in man, and also in Shabad's mice, than observation shows. It would seem that no entirely general influence can offer a complete explanation of established facts. Surely more specialized causes must determine the differences in geographical distribution observed among the various kinds of cancer which afflict mankind—must determine, for example, why throughout a large part of Wales the incidence of cancer of the stomach is over 40% higher than the average for England and Wales taken as a whole, while in the same region cancer of the vagina is some 30% lower than the average.[2] Surely highly specialized factors must be invoked to explain why one person gets this kind of cancer and another that. Nevertheless—and the situation is a curious one—we accept oestrone as a genuine cause, although it affects mammary glands from distant sites of injection and although we cannot say in any given case why the primary malignant focus arose just where it did rather than at some other point.

Another search for carcinogenic substances naturally present in the human liver is reported in two papers which are somewhat closely associated. One is by Des Ligneris[3] of Johannesburg and the other is by Hieger[4] of the Royal Cancer Hospital. The work derives from the fact, supported by a number of authorities, that throughout both Asia and Africa primary cancer of the liver is rare among Europeans, whereas among Malays in the Dutch East Indies and Bantus in South Africa primary cancer of the liver is common, especially in males. The cause of this difference in incidence is not known. Some think it may not be so much a question of race as of racial habits. It is said that the livers of practically all Bantus, even the supposedly normal, show cellular changes highly suggestive of assault by some toxin. Des Ligneris made extracts of both European and Bantu livers, omitting cancerous areas. He treated with alcoholic potash and then extracted with petroleum ether, a method suggested by Hieger. He painted mice and obtained a number of skin papillomata and epitheliomata with extracts prepared from both cancerous and non-cancerous Bantu livers, but no tumours with extracts prepared from non-cancerous Europeans. Hieger[4] used extracts of livers obtained from Bantus and from Europeans. Twelve tumours have appeared so far in 367 mice receiving repeated injections, but the figures are somewhat misleading when thus summarized. Extracts differed very greatly in potency. In one experiment tumours appeared in seven out of ten mice receiving extracts of livers from cancerous Europeans. The amount of extract obtained from a single liver is always small, so that even a very few mice can receive repeated doses only when several extracts are available. This explains the difficulty in tracking down the source of variations. It was thought that livers from cases of lymphosarcoma have given the most potent extracts.

It is difficult at present to trace the interrelationships between the findings of the workers in these several laboratories. All have investigated liver, but there have been differences in the source of the liver, in the methods of extraction, and in the methods of test. Hieger's results agree with those of Shabad in that tumours were indeed obtained in mice by injections of liver extract, but differ materially from his in that the tumours were all alike in type (sarcoma) and in that all appeared at the site of injection. Continued experiment should solve such perplexities.

HEALTH OF NEW YORK CITY

To statisticians and epidemiologists the value of health returns depends on their accuracy and the detail of their analysis. Time is needed to achieve these objects. But delay in the publication of vital statistics detracts from their interest as a measure of the recent progress of the public health. A statement of the incidence of infectious diseases in England and Wales in 1940 issued a few weeks ago by Sir Wilson Jameson was a gratifying break with tradition, but even in peacetime we have usually to wait some months after the end of a year before we receive somewhat sparse preliminary information as to birth and mortality rates. The Health Commissioner of New York (Dr. John L. Rice) has demonstrated that difficulties can be overcome. On January 1, 1941, he issued a preliminary report on the health statistics of the city for 1940, running to fourteen pages of foolscap and analysing in considerable detail the death rates by cause and the case rates of the common infectious diseases. When it is realized that New York, with a population of 7,392,000 persons, is nearly twice the size of the administrative county of London this promptitude is seen to be an achievement which should not be beyond the powers of our own larger cities. Provisional statistics issued at the close of a year either by local medical officers of health or by the Registrar-General would differ to such a small extent from the final figures that they need be in no respect misleading.

The New York statistics themselves are remarkable when it is remembered that the people of this city, like other large towns of the U.S.A., is of highly mixed origin and includes many negroes, Filippinos, and other coloured races with a high susceptibility to some of the most mortal diseases. The crude death rate was 10.3 per 1,000. Poliomyelitis continued to be infrequent, as it has been for the past five years, and, perhaps of more interest to us in the light of our recent experience, only forty-eight cases of cerebrospinal fever were notified. The deaths, numbering fifteen, suggest that reporting of cases may have been imperfect, if it can be assumed that chemotherapy is as efficacious in America as it is here. While the incidence of scarlet fever was heavy and measles rather high, the mortality from these diseases was unusually low, being 0.9 per 100,000 under 15 years of age for scarlatina and 0.7 per 100,000 under 5 years for measles. The prevalence of whooping-cough was a little below the average for the previous ten years, but it was much more fatal than measles, with a mortality rate of 10.8 per 100,000 under 5 years. A new low record for typhoid—0.2 per 100,000 at all ages—contrasts with a rate of 9.2 for appendicitis and illustrates the changing problems of preventive medicine. This is further reflected in the growing toll of the chronic diseases of

later life; with a uniform denominator of 100,000 the rate for diabetes has risen from 25.7 in 1930 to 42.0 in 1940, for cancer from 117.0 to 166.3, and for diseases of the heart, arteries, kidneys, and for apoplexy from 381.6 to 473.3. Dr. Rice points out that these increases are mainly due to the ageing of the population, although more frequent diagnosis is also a factor in the case of diabetes and cancer.

The most striking figures, however, are those for tuberculosis, diphtheria, infant mortality, and puerperal mortality. The death rate from all forms of tuberculosis has fallen from 73.3 per 100,000 in 1930 to 49.0, the respiratory tuberculosis rates being 64.2 and 44.9 in these years. The rates for New York in 1938 were 52.5 (all forms) and 47.7 (respiratory), as compared with 72.3 and 63.7 in the administrative county of London. The decline in diphtheria has been phenomenal. An intensive campaign for immunization began in 1929. The average annual number of cases notified in 1920–9 was 10,685 and the deaths 684. The subsequent decline has been rapid and practically continuous until in 1940 only 408 cases and ten deaths occurred, giving a mortality rate of 0.7 per 100,000 children under 15. This may be contrasted with the rate for England and Wales, similarly calculated, of 31.0 or more in recent years. Six health centre areas with an aggregate population of 1,400,000 have had no death from diphtheria for the past three years. While a substantial fall was already taking place in New York before immunization could have had much effect, it is certain that the continuity and the magnitude of the decline over a period of eleven years admit of no natural explanation. The infant mortality rate of 34.9 per 1,000 live births is the lowest so far attained. The steady fall in this rate is not associated with an exceptionally low birth rate, although it dropped from 20.8 per 1,000 of the population in 1920–9 to 13.7 in 1936 and gradually recovered to 14.5 in 1940. Some of the American States, such as Connecticut and Massachusetts, have equally low infant mortality rates, as have New Zealand and Australia, but the New York figure is likely to be a record for a large city. It is stated that over 60% of the infant deaths occurred in the first week of life, so that the number dying after the neo-natal period—that is, beyond 4 weeks of age—must be phenomenally low. A steep fall has also taken place in puerperal mortality from 6.4 per 1,000 live births in 1933 to 3.0 in 1940. The drop therefore began before sulphonamides were widely used in the treatment of puerperal infections, but it has been steadier since 1935 and resembles our own rate in this respect. The causes of puerperal mortality are not given, but they may be found to follow the same course as Dublin has revealed for the whole Federal Union[1]—namely, a more rapid decline of non-septic causes up to 1935, followed by acceleration of the fall of sepsis from that year onward. When it is remembered that obstetric practice in New York differs from ours in that a far higher proportion of confinements takes place in hospitals and domiciliary midwives are engaged for comparatively few cases, the contemporaneous improvement in maternal mortality casts doubt on some of the theories which have moulded opinion in this country.

TRICHINIASIS IN ENGLAND NOW

An outbreak of trichiniasis in this country, and the delay in recognizing it, make it advisable to remind medical men of some of its outstanding features. No disease is more likely than trichiniasis to pass unrecognized, because its symptoms, except in the severest cases, are commonplace in the last degree and easily explicable in a dozen other and apparently more probable ways. Its clinical manifestations are protean. The first effect of eating pork containing living cysts of *Trichinela spiralis* is upper abdominal pain with vomiting and diarrhoea; the latter often persisting, although its severity and duration are very variable, until the stage of invasion of the bowel mucosa by the mature female worms. Each of these produces a thousand or more embryos, which enter the blood stream and come to rest in the voluntary muscles. A second stage then begins, on about the ninth day after consumption of the infested meat, which is characterized by generalized muscular pain and tenderness and by fever. An apparently banal gastro-enteritis is thus succeeded by an equally commonplace attack of "rheumatism." This stage may be of any degree of severity, according to the number of parasites present. Lightly infested cases are almost certain to be disregarded, unless during a recognized epidemic. There may be nothing else than puffiness of the eyelids, and renal disease may be suspected, the absence of albuminuria dissolving the suspicion. The more severe compel attention by the height of the fever, the severity and wide distribution of muscular pain accompanied by swelling and marked induration, and sometimes by oedema, which affects the face, especially the eyelids, at an early stage, and sometimes much later the limbs and even the trunk. The condition of the muscles interferes not only with limb movements but with mastication and respiration; embarrassment of respiratory movements owing to involvement of the diaphragm and intercostals may lead to pneumonia. These severe cases, which also exhibit rapid wasting, are exceptional; in the majority the attack passes for one of rheumatism or influenza, although its duration—about five weeks—will eventually cast some doubts on the latter diagnosis. Other conditions provisionally diagnosed in the present outbreak are cerebrospinal meningitis, melancholia, paralysis, pyelitis. But the common syndrome is puffiness of the eyes and face, a raised temperature for two to three days, followed by eosinophilia. Whenever trichiniasis is suspected the first investigation should be a differential leucocyte count. Eosinophilia in this disease is extreme, 20 to 60% of these cells in a raised total leucocyte count being common. Medical men are urged to make use of the public health laboratories. Certain confirmation is obtainable only by finding adult worms in the stools, or by finding embryos, either in the blood by digesting a considerable volume and examining the deposit—a proceeding which is applicable during the stage of invasion—or later in muscle. This last method is easier and more certain, and is usually carried out by a vertical incision over the lower part of the deltoid and the excision of a small portion of this muscle. Embryos are identifiable with the low power of the microscope in teased-out or "press" preparations, either free if infestation is very recent or in process of encystment. Purging, especially with large and repeated doses of calomel, is of value in the early stages; no treatment is known which has the slightest effect on embryos already in the tissues. In the presence of an epidemic of trichiniasis any patient complaining of gastro-intestinal disturbance after eating pork in any form should at once be purged; the majority of the parasites can be got rid of by treatment instituted before they mature. For prevention it is necessary to ensure that all pork and sausages are thoroughly cooked. Trichiniasis is notifiable.

FOOD IN THE SHELTERS

We publish elsewhere in this issue a survey of the canteen services in London shelters. The basis of good health, as has so often been said before, is good food, and there can be no doubt that in peacetime the people who now inhabit the shelters were not eating the right kind of food for healthy development of mind and body. This was partly the result of economic circumstances, and partly the result of ignorance. The fact that large numbers of people now live in shelters and eat in them provides an excellent opportunity for studying the dietetic habits of the poorer sections of the population, and it soon becomes evident that they prefer the kind of food experts in nutrition frown upon, and do not take readily to more suitable kinds of foods that are put before them by the numerous agencies conducting the canteen services. For example, tea and cakes are demanded in place of other more nutritious dishes. There is, too, a superstitious reverence for certain meat extracts, a superstition based upon the compelling influence of modern advertising. There is no doubt that uneducated people—and even educated—are inclined to take literally the slogans that stare down at them from attractive posters on hoardings and other places.

It is perhaps too easy to attribute all bad dietetic habits to ignorance, because the products of refined flour and refined sugar are cheap and filling, and the choice of these cannot be said to lie in any innate preference. The shelter problem, however, does give all those concerned in this matter a further opportunity for educating a large section of the population, from the point of view not only of improving their health now but also of teaching them to demand a more satisfactory diet when peace returns. The Ministry of Food is setting a magnificent example in its attractive advertisements in the lay press. Further education of the poorer section of the population may be undertaken through the medium of leaflets, films, and lectures, and this will have to be persistent in order to overcome the settled customs and prejudices of those most in need of assistance.

The Ministry of Food is now undertaking to prepare on a large scale a canned vegetable soup to be sold in shelters and to be distributed in an emergency at a very low cost. The basis of the soup is milk, oatmeal, and potato, and such other vegetables as carrots, beans, cabbage are included. One portion of this soup with a piece of brown bread will provide approximately 500 calories, and will make a very substantial contribution to the day's requirements for calcium, iron, and vitamins A, B_1, and C; the soup has been made up with this end in view. It is to be hoped that when peace comes caterers with a sense of social responsibility will follow this example and market as nutritious a vegetable soup at an economical price, and in its preparation take the kind of expert advice which is now at the disposal of the Ministry. As is clear from our survey, there are a number of bodies engaged in the canteen services—for example, the Friends' Ambulance Unit, the Women's Voluntary Services, the Salvation Army, the London Passenger Transport Board, the Milk Bars Association—and in some instances local caterers. No one has anything but praise for the good work that all these bodies are doing, and for the high-minded motives behind it. But here again there is a divergence of food customs depending upon the knowledge and interest in dietetic matters. At the risk of appearing invidious we would single out the extremely thoughtful work that is being done by the Friends' Ambulance Unit. Behind the work they do there is evidence of intelligent application of modern knowledge on nutrition, and sympathetic attempts to educate the shelter population. Such an observation leads to the conclusion that the people who run canteen services, and caterers themselves, also could do with some elementary instruction in the same subject. The fundamentals of nutrition are simple. There is nothing recondite about them, and popular writings during the past few years have brought them before a wide public. As a profession we can individually and collectively continue to force these matters on all sorts and conditions of people But one group in the profession—the medical officers of health—are perhaps in the best position to bring their influence to bear in the health areas they serve.

DIABETICS IN WARTIME

The diabetic shares the common experience of disorganization of life and privation in wartime, but some of the prevailing conditions involve him in special dangers. These were discussed at the last meeting of the Medical Society of London in a short paper by Dr. Wilfrid Oakley. The effect of longer hours of work, he said, could be guarded against in the case of the diabetic by readjustment of meals and the carrying of extra carbohydrate rations, biscuits and chocolate, if obtainable, being the most convenient. As for long hours in shelters, he said that he had noticed among out-patients at King's College Hospital in the early days of air raids that the morning specimens contained large amounts of sugar, suggesting a tendency towards indulgence in food, but as the patient became used to his new mode of living the sugar content began to fall back again to its usual level. The danger to the diabetic if he becomes an air-raid casualty is that he may be admitted to hospital in an unconscious state without anyone knowing that he is a diabetic, and go on to a state of coma which may be attributed to the effect of his injuries. The Diabetic Association first circulated cards which diabetics might carry on their persons, but these have now given place to a metal disk to be worn on the neck or the wrist. A wartime possibility is a temporary breakdown in supplies of food or of insulin, and this can only be guarded against by iron rations (a sealed tin of biscuits of known carbohydrate value and a month's supply of insulin). Dr. Oakley pointed out that the chief dangers to the diabetic in wartime were hypoglycaemia and ketosis. Hypoglycaemia due to the use of zinc-protamine-insulin was not greatly to be feared if only small doses, say 20 units, were given, with regular carbohydrate feeds every three or four hours and a bedtime feed of 10 to 20 grammes: but when the dose exceeded 20 units hypoglycaemia was likely to occur, and with doses of between 30 and 40 units was a real danger. Nearly all the tragedies with zinc-protamine-insulin had been the result of giving rather heroic single doses instead of smaller doses of a combination of zinc and soluble insulin. The danger of hypoglycaemia was greater and the hypoglycaemia itself might be more severe in patients who were treated with protamine insulin, and some people had urged that protamine insulin be not used during wartime; but the advantage of a method of treatment requiring only one injection over a method which necessitated at least two, more than compensated for possible dangers. It was far easier to take carbohydrate in a portable form to the shelters or workshops than to give an injection of insulin under the same conditions. Again, the form of treatment with which the patient was already familiar was always to be preferred. At the same time, Dr. Oakley did not think that protamine insulin should be given to new out-patients without a reasonable period of stabilization in hospital or nursing home. He gave the figures of the deaths of diabetics who had been attending King's College Hospital. During the war period from September, 1939, to the end of 1940 the deaths numbered 67. For the four years 1935–8 the annual numbers of deaths were 65, 62, 63, and 84 respec-

tively, so that there had been a fall during the war period. In not one instance was the death of a patient due to hypoglycaemia as a result of using protamine insulin in wartime. Dr. Oakley added that it was most desirable that the diabetic taking protamine insulin and regularly using the same shelter should inform some responsible person, such as the shelter marshal, that he was a diabetic. Secretiveness about being a diabetic is pardonable in peacetime, but is apt to be dangerous in war.

CONTROL OF INFECTION IN SCHOOLS

While the general principles underlying the prevention of the spread of infection were settled before the bacteriological era, advancing knowledge has led to specific methods for the control of each infectious disease, or group of diseases, which are not applicable to others. The recognition of this specificity leads to economy of practical effort. The Memorandum on Closure of and Exclusion from School issued jointly by the Ministry of Health and the Board of Education, which first appeared in 1909 and was last revised in 1927, recognized the point, but new discovery and the practical experience of medical officers of health and school medical officers have led to representations during the past year that this publication should be overhauled. So far there is no indication that this is being done. The reason is obvious, but the Medical Officers of Schools Association, which is concerned with preparatory and public schools, has not been deterred by present circumstances. Their Code of Rules was first issued in 1885, has undergone revision and enlargement on several subsequent occasions, and now appears in new form.[1] It deals briefly with certain general matters, such as hygiene in schools, the infirmary, sanatorium or sick house, examination of entrants, general precautions against infectious disease and measures to be taken on its occurrence, and then summarizes, in alphabetical order, the salient points on each common infection. Since the Revision Committee of the Association contained specialists in infectious diseases as well as school medical officers its deliberations have resulted in a code which embodies modern knowledge and is also thoroughly practical. It will be useful not only to those for whom it is primarily intended but also to health departments which are concerned with similar problems both in rate-aided schools and in the many other institutions for which they are responsible. Reference may be made to one or two issues of general interest. On the question of dispersion of pupils, which aroused much controversy some years ago when poliomyelitis invaded certain public schools, the code is cautious, but on the whole is against the break-up of schools except in very unusual circumstances. It recommends segregation of meningococcal carriers, a procedure which, although not now generally favoured, is probably advisable for closed susceptible communities of the kind in question. It records, without approval or disapproval, the view of some public school medical officers that contacts of non-notifiable infections should not be excluded but observed in school. While the diversity of the manifestations of streptococcal infection is adequately discussed, more attention might have been paid to the growing body of evidence that streptococci and other micro-organisms may be spread not only by droplets, fomites, and the persons of attendants, but also for quite long distances through the air in droplet nuclei. As minor criticisms, it may be pointed out that the list of diseases requiring to be notified is out of date, confused, and repetitive; that Salmonella infection of animals subsequently slaughtered for human food is ignored as a cause of food poisoning (and it appears to be assumed that the existence of true human carriers is established); and that the impression is conveyed that accredited milk is safer than ordinary commercial milk. On comparing the incubation periods given for the various infectious diseases with those stated in the official memorandum and other publications, one cannot avoid being struck by the marked discrepancies in some instances. After so many years of clinical and epidemiological observation some finality should have been reached, and yet there is no list, including that given in the code, which is correct in every particular. The common range of the period and its extreme limits, if they are known, should be given for each disease. If there is any doubt, this should be recorded.

THE PROBLEM OF CHRONIC RHEUMATISM

In a recent communication on the subject of focal infection in rheumatic diseases Reimann and Havens[1] cast doubts on the aetiological importance of infected teeth and tonsils. The evidence they marshal is impressive, but they admit that at present no final conclusion can be reached. It is generally conceded that both tonsillectomy and extraction of teeth have been carried out in the past to a much greater extent than appears justifiable in the light of our present knowledge. It is obvious, however, that an infected tonsil or tooth socket which is discharging pus into the mouth must have a harmful effect on the mucous membranes of the alimentary tract, especially if there is achlorhydria, in which case radical treatment is necessary. Osgood, who discussed the medical and social problems of chronic rheumatism in his Nathan Lewis Hatfield Lecture of the College of Physicians, Philadelphia,[2] believes that gastro-intestinal disorders are probably of aetiological importance, particularly in association with faulty alimentation; he quotes Holbrook, who, in a wide experience, found that a majority of his patients with rheumatoid arthritis gave a history of gastro-intestinal dysfunction. Too much importance has been attached to areas of rarefaction round the roots of the teeth. They are commonly assumed to represent periapical abscesses, but this is by no means always the case, and Sharp and others have shown that with proper treatment there may in time be restoration of the bone to its normal density. Cecil, who formerly held that removal of such infective foci was essential in the treatment of rheumatoid arthritis, has recently stated in an article written in collaboration with Angevine that "in no instance was the course of the disease altered or the patient cured when supposed foci were removed." Reimann and Havens suggest that the lowered resistance which is commonly a forerunner of rheumatoid arthritis may lead to infection of the teeth, tonsils, or other organs, and that these foci, as well as the arthritis, may be due to some common cause—a new point of view which deserves serious consideration. In the light of the evidence advanced by these authors and others it is clear that the problem of focal infection calls for re-examination. Osgood believes that the unknown factor in causation will probably prove to be biochemical rather than bacterial. He urges that there should be financial help from public funds for the fight against rheumatism, and that the expenditure could be justified on grounds of economy alone.

The Hunterian Oration, entitled "Charles White of Manchester and the Development of Provincial Medical Education," will be delivered before the Royal College of Surgeons of England at the Royal Society of Medicine, 1, Wimpole Street, W., on Thursday, February 13, at 2.30 p.m., by Prof. A. H. Burgess.

FEEDING OF THE SHELTER POPULATION

A LONDON SURVEY

The supply of nourishing food to the immense population which nightly congregates in the London shelters is an important phase of the air-raid problem which confronts the authorities. The work has been undertaken by voluntary bodies as well as professional caterers, and below we give some account of these services.

In the Tube shelters from 80,000 to 120,000 people are catered for every night. On all stations used as shelters there are facilities for making tea and cocoa and also soup. Tea is served at night and in the early morning, and cocoa and soup on alternate evenings. It has been found that the preference of the shelterers is for a cup of tea with such food as meat pies or sausage rolls early in the evening, and cocoa or soup before they go to sleep. When the service began tea and cakes were all that could be provided, but a greater variety can now be offered, and the consumption of more nutritious foods is gradually increasing. Milk is supplied to child and adult shelterers if the nurse at the first-aid post certifies it as desirable and necessary.

The London Passenger Transport Board acts as the agent of the Ministry of Food for this service, which is undertaken by a special staff. Five trains are used to transport the food to the stations from depots in London and the suburbs. It is only on Tube stations that, to avoid congestion on the platforms, the food is taken round to the shelterers, the liquids being carried in two-gallon cans and the food in baskets. Elsewhere the food is usually served from a counter.

The Salvation Army is responsible for the feeding in a very large number of London shelters, and has a similar organization in large provincial cities. The work in London was started, at the request of the police, a few hours after the beginning of the intense air-raiding. It was undertaken to meet the immediate need—the Salvation Army is not advised by dietitians—but it has now been brought within the Ministry of Food scheme. In some places the local authorities supply the equipment; in others the Army supplies its own. In large shelters an improvised fixed canteen is installed, while mobile canteens look after the small ones. The food supplied consists of sandwiches with various fillings, sausage rolls, meat pies, buns and cakes, with tea. It is as wholesome, and served as cleanly and palatably, as possible. As a general rule arrangements are made only for heating water; all cooked foodstuffs must be prepared beforehand.

One mobile canteen run by the Salvation Army visits seven shelters in the dockside area. It works under great difficulties. Its "kitchen" is a surface shelter streaming with water. Tea is made in insulated urns in the "kitchen," where sandwiches are also prepared. The van calls at the shelters and serves the people direct. There is reported to be a huge demand for tea and cakes among the very poor in this area, while sandwiches are a poor second. The shelters are also visited in the early morning with a similar bill of fare, but the sales are then small. The demand for tea and sweet cake in the morning is, however, quite remarkable. This may be understood in the case of those who have their own works canteen to fall back upon for more substantial food, but not in the case of others less well provided.

A Model Canteen

The work of the Women's Voluntary Services so far as shelters are concerned is concentrated principally in one London borough. This body has established a model canteen in one of the large West End shelters, where soup is served and the eating of brown bread is encouraged by distributing it free with the soup. The soup is made in the W.V.S. soup kitchen from bones and vegetables. The shelterers are encouraged to eat apples because they clean the teeth, and hot drinks are made with as much milk as possible. Meat pies, fish cakes, "hot dogs," and sweet cakes can also be obtained, and in the morning porridge, bacon and fried bread, and marmalade sandwiches are available. More than forty mobile canteens run by the W.V.S. are serving surface and trench shelters. Tea and coffee are sent out in thermos urns, soup is distributed cold and warmed up in the shelters, and sandwiches and the like are also provided. The W.V.S. works in touch with the Ministry of Food, and will be trying out its recipes in the model canteen. Its primary object is to give—and to educate the people to ask for—food of good nutritive value. The organization has the services of expert dietitians.

The Friends' Ambulance Unit is responsible for the feeding arrangements in twenty-one shelters in the East End and City, and has fixed canteens in the large shelters. All the buying is done at the Unit's headquarters, and the canteens are supplied at cost price. In the larger shelters served by the mobile canteens a tea urn is left with a box of food, for which some person in the shelter is responsible. The profits—that is, the difference between the cost to the shelter and the payments by purchasers—are used for the benefit of the shelter; the prices are fixed by the Unit. In the very small shelters the people are served by the van direct. The food includes sandwiches with various fillings, and a popular delicacy is a roll cut open and a sausage inserted (the sausages are grilled in the kitchen at headquarters and carried round in a tin placed in an improvised "haybox").

In the early mornings porridge with milk and sugar is served in the fixed canteens and also carried round to the shelterers, with tea, sandwiches, and cake. The morning demand varies greatly from shelter to shelter for no apparent reason. In one of two shelters in one street served with morning porridge the dish is eagerly accepted, while in the other the people "will not look at it." The Friends' Unit also has qualified dietitians on its staff.

A London borough which has only small shelters has given the catering over to a number of local people, whose job it is to feed the working-class population. The prices are fixed by the local authority, and are approximately 1½d. for liquid refreshment, 1d. and 2d. for cakes, and 2d. for sandwiches. Electric hot-points and boiling-points have been installed, together with a good cupboard for storage and an improvised counter. There is an evening and an early morning service according to the requirements of the people in a particular shelter. Soup is available in some of the shelters and has been asked for in others. No voluntary body is operating in this borough; the authority is satisfied that the people are getting what they want.

Twenty-eight shelters are catered for by milk-bar proprietors, who have found that the beverage preferred by the vast majority of the people is tea; the proportion of coffee, cocoa, and milk asked for is very small. For soup there is practically no demand. The wastage of food at first was considerable. A good variety was provided, but for a number of reasons it was not consumed, and the proprietors have had to cut the bill of fare to meet the demand, which is mostly for a hot drink and sweet cakes or biscuits. A morning service is given in these shelters, but the demand is small.

Individual Enterprises

At a shelter under one of the large London markets there is an excellent canteen which was presented by a City merchant and is staffed by voluntary workers. A very good vegetable soup is sold, the recipe for which was worked out by the Ministry of Food. Fish cakes and portions of fried fish cooked in an adjacent staff kitchen, wholemeal bread rolls and sandwiches, and cake are provided. Tea is available, but during our visit milk, soup, and cocoa seemed to be as much in demand as the cup which is supposed above all to cheer the shelterer.

At an East End settlement visited thirty gallons of soup were being made in large coppers as carefully as if in a hospital. This soup is carried round in insulated urns to a large number of shelters fairly late in the evening so

that the people can go to sleep on soup rather than on tea. If there is a raid the soup, with coffee and sandwiches, is available for A.R.P. workers and firemen. Sometimes a bland soup is made, at others the cook puts in flavourings. The vegetables are not mashed into a pulp, but left in small lumps, because the people "like something to bite into." It is sold at one penny a cup, with a piece of bread, and salt is available. "They won't look at it if they can't put salt into it."

A well-known Methodist minister in Westminster has long interested himself in the feeding in shelters in his neighbourhood, and, noticing the predominance of starchy foods consumed, he and his wife two months ago resolved to counteract it by making a vegetable soup in which bones had been boiled down. This is served early in the evening as the workers arrive, and on the average rather less than half the people take advantage of the soup, the charge for which, with a piece of bread, is twopence. If the nurse in these shelters notices anyone "off colour" a milk drink is provided free of charge. The food in these shelters is of the usual good quality associated with voluntary efforts.

In another district the "Woolton sandwich," the filling of which consists of grated raw vegetables bound with chutney, is popularized by posters in the shelters. South of the river local fish-and-chips friers in white coats with nicely-done-up packets follow their bombed-out clients into the shelters; rolls with hot bacon inserted are considered a delicacy elsewhere, and at another shelter faggots made from butcher's offal and herbs have pride of place in the menu. Alike in districts that could be described as poor and in others which would be considered well-to-do, potatoes baked in their jackets served hot with a dab of margarine and sprinkled with salt and pepper are very popular. In one shelter baked bread pudding made from a mixture of broken pieces of brown and white bread, flavoured with spice, a little sugar, and dried fruits, is considered a dainty dish, served either hot or cold.

General Conclusions

From our survey it is fairly obvious that there is a line of demarcation between the bodies which are advised by experts on food and which have foremost in mind the nutritional welfare of the people they are serving, and those which are bound by the necessity of paying for their equipment and labour and covering expenses. Where a voluntary agency is at work the increase in the variety of food and its higher nutritional value are marked; more care is also taken to keep the food wrapped and clean.

That there is a good deal of difficulty in this form of catering is also evident. Preparation has to be made for air-raid nights, whether air raids come or not, and the food has to be of such a nature that it can be re-issued the next night and will be appetizing. Many of the smaller shelters are tucked away in side streets difficult of access; kitchen accommodation is extremely limited, and there are other difficulties. The fact that practically every shelter in London is now provided for in one way or another speaks volumes for the ingenuity and patience of those responsible, to say nothing of the courage and driving skill of the workers in charge of mobile canteen vans on dark wintry nights and during air raids.

Fut Ang Chu and Jui' P'ing (*Chinese med. J.*, 1940, **58**, 39) state that of thirteen children in an orphanage inoculated with a vaccine prepared by Sauer's method before an outbreak of whooping-cough none developed the disease in spite of continuous and prolonged exposure, whereas twenty-three (67.6%) of thirty-four non-inoculated children whose age, mode of living, and degree of exposure were much the same as those of the inoculated children developed typical pertussis. The serum agglutination titre for *Haemophilus pertussis* was found to increase during the course of the epidemic in seven of the inoculated children, indicating that they had been exposed. The remaining six also showed increased agglutination titres, but they had been given an additional dose of vaccine during the early part of the epidemic.

SPECIAL ANTI-GAS RESPIRATORS

The Ministry of Home Security has just issued a circular to local authorities announcing that two new devices are now available for issue to persons who are unable to wear standard respirators.

Two Types of Mask

The first is a standard civilian respirator with the addition of an outlet valve. Breathing difficulties experienced in wearing a respirator by persons with respiratory troubles are in general due more to the expiratory resistance than to the inspiratory resistance, and the new respirator with outlet valve overcomes a great part of these difficulties. So far as resistance to breathing is concerned, this respirator compares favourably with any other type, and should be adequate to meet all but the more severe respiratory troubles.

The second is a helmet respirator which is designed for those who, because of tracheotomy, facial deformity, or severe cardiac trouble, etc., are unable to wear any respirator of ordinary type. The problem of protecting such persons against gas has naturally been under active investigation by Government research workers for a considerable time. It has also attracted some attention in the medical profession, and in particular descriptions have been published of various devices for adapting standard respirators so that they can be worn by persons who have undergone tracheotomy. These devices have mostly been of the type which involves the fitting of a gas-tight pad, with breathing tube, over the tracheotomy orifice. It is, therefore, of interest to note the lines on which this new helmet respirator has been designed in the Government research establishment responsible for its development.

The Problem in Cases of Tracheotomy

The investigation of the general problem of protecting persons who cannot wear standard respirators included a careful study of the tracheotomy type. From an examination of a number of typical cases it was apparent that only a small proportion could be fitted in a gas-tight manner with a pad over the tracheotomy orifice. Many persons who have had a tracheotomy performed have thin shrunken necks with the tracheotomy opening deeply recessed, while others have the wound still unhealed or discharging and requiring frequent clearance to avoid blockage. Should blockage occur while wearing the pad device the patient might have to risk suffocation or remove the pad and risk inhalation of gas, and this is a serious objection to this type of device.

It was also evident that a pad device would require individual fitting by a surgical appliance maker, and that the efficiency of the fitting could be proved only by a test in a respiratory irritant gas—for example, chlorine—since C.A.P. in concentrations which are highly lacrimatory does not irritate the respiratory passages. Such a test would be impracticable for general use. Finally, owing to the opening being situated at the base of the neck in the majority of cases, it is normally covered by the clothing, and access to it for adjusting the pad would accordingly not be easy in an emergency.

It was clear, therefore, that for general application the only type of device which could be relied upon for complete protection in all cases was a hood, which enclosed the head and extended downwards so as to cover the tracheotomy opening, provided with a means of supplying air to the interior. A device of this type was designed and successfully submitted to comprehensive tests. As a result the helmet respirator has been produced and is now available for distribution to suitable cases upon production of a medical certificate.

The Helmet Respirator in Operation

It consists of a hood of impervious rubberized fabric, suitably stiffened at the corners so that it retains its shape and does not collapse on to the wearer's head, fitted with non-inflammable eye-pieces and a rubber air-supply unit by means of which the wearer pumps air to the interior. Attached to the hood is a skirt of porous fabric which is shaped to fit the wearer's shoulders, and the respirator is secured to the person

by strings which draw the back and front portions of the skirt together under the armpits. A standard respirator container is fitted inside the air-supply unit so that all the air passes through the container before entering the hood. The air enters the hood immediately in front of the wearer's tracheotomy opening, which was found to be an important point affecting comfort. The air leaves the hood around the bottom edge through the porous fabric of the skirt. The hood is made of such a size that the wearer can, if desired, cease pumping for a few minutes without ill effects. Should blockage of the tracheotomy tube occur while wearing the helmet respirator, the wearer can readily slip one hand up inside the hood in order to free the blockage.

Persons who have undergone tracheotomy form only a small proportion of those who cannot wear a standard respirator. Others may be classified in the following groups: distorted head—for example, acromegalics; large tumours of face and neck; old operation cases leaving gaps—for example, removal of part of the jaw—and tender scars resulting from injury, war wounds, etc.; severe respiratory disability, as in acute asthma, phthisis, and old cases of empyema. The helmet respirator is intended for use in all such cases, and its suitability for the purpose has been fully demonstrated by trials. It is of particular benefit in cases of acute asthma. In addition, it should find application in hospitals for persons with severe facial and head injuries. It must, however, be emphasized that because of supply difficulties resort should not be had to the helmet respirator where the ordinary respirator with outlet valve will suffice.

Both the civilian respirator face-piece with the outlet valve and the helmet respirator will be provided at the discretion of local authorities, and not as a right, to members of the public who need them on medical grounds, on production of a medical certificate, provided the present respirator is surrendered in serviceable condition. The form of certificate, as set out in a Ministry of Home Security circular, is as follows:

Medical Certificate

I certify that

(Name) ..... of

(Address) .....

.....

is suffering from (specify disease or condition*)
and on that account is incapable of exerting the respiratory effort necessary for wearing the ordinary civilian respirator.

Delete one of these { The case would be met by a respirator with an outlet valve.
{ The case appears to require a respirator helmet.

Signature and qualifications of registered medical practitioner .....

Date .....

* The kind of conditions requiring a face-piece with outlet valve are: chronic asthma, fibrosis of the lungs, tuberculosis of the lungs, cardiac disease, severe anaemia, advanced age and infirmity, extreme corpulence. The kind of conditions requiring a respirator helmet are: tracheotomy, facial distortion (whether natural, due to tumours, or the result of surgical operation), extreme dyspnoea, severe cardiac disease, advanced tuberculosis.

The circular deals with the charges that will be made where the present respirator is not surrendered in serviceable condition, and with the needs of hospitals for the helmet respirators, it being estimated that a substantial part of the demand for the latter will arise in institutions. The circular concludes with a recommendation that medical officers of health should get in touch with members of the local medical profession and arrange for them to see the new devices and to form a common policy on the giving of certificates.

The Ministry of Health has asked local authorities for simple four-weekly totals of new notifications of tuberculosis, the period of the first return to be for the four weeks ending January 25, 1941. For comparative purposes similar returns of past notifications covering the four weeks ended January 28, 1939, and succeeding four-weekly periods are also to be supplied. Copies of the circular containing these directions (No. 2257) have been sent to medical officers of health.

PROBLEMS IN RECEPTION AREAS

PUBLIC HEALTH AND SOCIAL WELFARE

It would be idle to disguise the fact that evacuation on a large scale in this country is neither a natural nor a popular process. The clash of the London and the country woman when brought into the same kitchen, and of their children when attending the same school, might well have doomed the experiment to failure, yet thanks largely to the efforts of voluntary associations and local authorities, and also to the mutual forbearance in the majority of cases of the people concerned, it has largely disappointed the gloomy prophets. Still, there are crooked places in the home counties and elsewhere, and to make them straight the Minister of Health recently appointed a small committee under the chairmanship of Mr. Geoffrey Shakespeare, M.P., whose reference was to inquire into the welfare of evacuated persons.

The committee, which has just reported,[1] visited these areas in seventeen counties. The normal population of the areas visited is about six and a quarter million, and this has been swollen by roughly one million evacuees who have been officially billeted, and some 600,000 unorganized evacuees who have made their own arrangements.

Welfare Arrangements

The report has a good deal to say about billeting and requisitioning of houses, and urges the establishment of what it calls buffer hostels to relieve temporarily the strain on hostesses. Adequate welfare facilities, it declares, are the essence of good reception arrangements, and these should include the establishment of clubs for mothers, combined where possible with communal feeding, nursery centres, and bath houses and laundry facilities on a communal basis. There are, in fact, already 265 communal feeding centres in the reception areas. There is need for more welfare officers to be appointed to the regional staffs of the Ministry of Health. Some women welfare officers were appointed last summer to the Ministry's staff in the regions most affected, and their number has been increased during recent months, while others have been appointed by local authorities. But there is a shortage of women for this service. The suitability of hospital almoners and women public health officers for these posts is emphasized.

One great problem is that of the difficult or special cases not suitable for private billeting. These include, on the one hand, children suffering from skin diseases, who should immediately be sent to premises converted into sick bays, and, on the other, those addicted to bed-wetting, the emotional children, and the delinquent, who require special care under trained supervision. The committee urges the establishment or taking over of hostels by the county authority in order that different types of children may be treated separately, and the provision of one hostel at least in each county for difficult older boys. Already the number of hostels for difficult children in the reception areas is over 500.

Strenuous efforts have been made to dispatch parties of children in a cleaner and healthier condition than at the beginning of the war, but a new factor has now entered—namely, the evacuation of children, not from schools, but from shelter life. The committee considers that where possible children should be received in emergency hospitals, or temporary hostels in which they can be rested and cleaned before being billeted, and that there should be powers to examine, and if necessary to cleanse, adults who may be in a state unfit for billeting in private homes. Actually powers were taken last December for the compulsory medical examination of children in shelters and those thought to be affected in health by war conditions, and for the cleansing of adults frequenting shelters.

Hospital Services and Medical Treatment

Emergency arrangements to deal with sudden epidemics have been enjoined by the Ministry of Health on all local authorities, and buildings have been assigned for this purpose; it is

[1] *Report on Conditions in Reception Areas*, H.M. Stationery Office, 3d. net.

recommended that these buildings be immediately adapted for this use. Accommodation for infectious diseases is still insufficient, and it is considered that there should be provision in all the regions for measles cases where there are complications or where the billets are unsuitable for home nursing. It is stated that the Ministry is making every effort to increase the accommodation available and has reserves in view. The District Medical Service should be extended, and the cost of its extension should not fall on local rates; also, where the burden of the treatment of official evacuees falls on the voluntary hospitals it should be chargeable to the evacuation account. Those who subscribe to voluntary hospitals contributory schemes in the sending areas should be able to enjoy the benefits in the reception areas. This last recommendation is said to be under consideration, and as for the District Medical Service, local authorities were asked last November to review their services and extend them as necessary, the additional costs being reimbursed in full by the Exchequer.

The provision of maternity homes is said to be generally sufficient, but more ante-natal and post-natal homes are required. The need for such hostels was impressed on local authorities at the beginning of the war, but shortage of suitable accommodation is again the limiting factor. The number of maternity homes in reception areas is 130. One difficulty is that the burden of billeting the mothers and babies when they leave the maternity home falls on the one district where the home is situated, and the committee considers that arrangements should be made for placing these cases over a wider area. Many authorities have hostels or clearing houses where elder children can be billeted during the mother's confinement, but more temporary residential nurseries are required for children under 5 to serve the same purpose. There are nearly 200 residential nurseries in the reception areas, and the number is being increased as rapidly as suitable premises and trained staff can be found.

A general increase in the scales of allowances for the boarding of unaccompanied children would probably have gone a long way to reconcile the reception areas to the strain which has been put upon them, but the committee does not see its way to make such a recommendation. It does, however, recommend that the allowance of 5s. a week to the householder for the nursing of a sick evacuee child should be increased on a medical certificate that extra comforts or nourishment are needed. The Ministry states that the case for increasing the home nursing allowance is being investigated.

Local News

IRELAND

Honorary Degrees

Dr. Gordon M. Holmes, F.R.S., Dr. F. M. R. Walshe, and Prof. Ernest Hey Groves are the recipients of the Honorary D.Sc. of the National University of Ireland, the two former "in view of their eminence as neurologists and in recognition of their valuable contributions to medical literature," and Prof. Hey Groves "in view of his eminence as an orthopaedic surgeon and an internationally recognized authority on the literature of the subject."

Eire Health Statistics

The public health statistics for Eire for the year 1938–9 show improvements in many directions. Notifications of the principal infectious diseases totalled 8,065, as compared with 8,677 for 1937 and 8,924 for 1936. The figures for diphtheria were, however, disappointing, 2,983 cases being notified as against 2,511 in 1937. The report of the Department of Local Government and Public Health states that diphtheria continues to be "one of the major problems of public health" and that "the spread may in part be accounted for as resulting from the intensive propaganda that has been carried out recently against immunization." Decreases were recorded in the notifications of typhoid fever, scarlet fever, and acute primary and influenzal pneumonia. The death rate from all forms of tuberculosis was 1.09 per 1,000 of the population, the lowest rate ever recorded. Deaths of infants under 1 year were fewer in 1938 than in 1937 and 1936, the rates being respectively 67, 74, and 73 per 1,000 births. The infant mortality rate for the county borough of Dublin was 96, and it is suggested in the report that a causative factor is the failure of Dublin mothers to breast-feed their infants. Progress is reported in the administration of free-milk schemes, maternity and child welfare approved schemes, and the work of the school medical service.

ENGLAND AND WALES

Mental Health in Wartime

In a Chadwick Lecture with this title given on February 4 at the Royal Society of Tropical Medicine and Hygiene, Sir Walter Langdon-Brown said that the ostensible reason for the outbreak of a war was never the real one. Emotional causes were transformed into alleged rational ones, although deep-seated and hidden causes of antagonism were at work. The fierce fanatical outbreak of nationalism in this century became comprehensible as a frightened response of the nationalist segregating impulse against the demand of the evolutionary process towards internationalism. If a normal healthy impulse was forcibly repressed it came to the surface again in an abnormal pathological form. Thus the collective values which ruled the world up to 1914 had been swept away, and people had become hardened to shameless persecutions, betrayals, and predatory invasions in the name of the deified State. The division that arose was between nations who considered that the individual existed for the State and those who thought the State existed for the individual. The background against which the present war was being waged was a moral and spiritual disease in Europe resulting from attempts to stem the tide of the evolutionary process. Both constructive and destructive impulses were always present in the human mind, and to-day the latter had the upper hand. When war came the gregarious instinct was always interrupted and nations looked for a leader. He might not have the characteristics attributed to him, but he must have an emotional appeal. There was also a tendency to the making of myths and to reliance on rumour. Information was the best antidote, and was the more needed now that wireless had enormously increased the power of the lie. The greatest enemy to be overcome was fear, which was really an exaggeration of a normal protective impulse. For years insidious propaganda had been instilling fear into the nations. The fear of being afraid was particularly distressing, and the best remedy was action as a member of a community. Pessimism and fear were chiefly prevalent among those who were not contributing to the national effort. It was already clear that an exaggerated estimate had been formed as to the liability of air raids to produce nervous breakdowns, and the way the people were facing them was evidence of this. The nature of panic fear called for consideration, and certain steps taken by the Government deserved criticism in this respect. The importance of everything designed to maintain physical fitness in the cave-man's existence to which we were now condemned could hardly be overstressed; for to revert also to the cave-man's primitive ideas of sanitation would indeed be treason to Chadwick's memory. Vitamin A had a very real value in promoting adaptation of the eyesight to the blackout. Various other measures were discussed in relation to the maintenance of mental health.

J. Pley (*Thèse de Paris*, 1940, No. 338), who records three cases in patients aged from 29 to 44, illustrated the rarity of traumatic enophthalmos by the fact that Birch-Hirchfeld in 1930 was able to collect only 164 cases from the literature. It consists of a progressive sinking-in of the eyeball following an injury in the region of the orbit with an interval of varying duration. A lesion of Tenon's capsule appears to be the most logical explanation of the condition. Besides this indispensable lesion are secondary causes such as paralysis of sympathetic origin, atrophy of the intraorbital fatty tissue, and cicatricial retractions.

Reports of Societies

FRACTURES OF THE JAW: SURGICAL AND DENTAL TREATMENT

At a meeting of the Section of Odontology of the Royal Society of Medicine on January 27 Mr. A. H. McINDOE gave a review of 119 cases of fracture of the upper or lower jaw and of their surgical and dental treatment at an Emergency Medical Service Maxillo-facial Unit during the period from the outbreak of war until the end of 1940. He spoke appreciatively of the help given by Sir Harold Gillies and Mr. Kelsey Fry, who had guided the surgical and dental policy of the unit. The results obtained were not due to one person but reflected the combined efforts of a team.

Statistics of Cases

Fractures of the mandible numbered 82, of the maxilla, 37; in 7 cases both mandible and maxilla were fractured. Of the 119 cases, 68 were without other injuries. The associated injuries varied from extensive soft-tissue lacerations to fractures of long bones or skull. The greatest number of cases were among fit young men on active service, but a number also occurred among older people during the bombing of the civilian population. The causes in 43 of the cases were bomb and shell fragments and mine explosions; in 9, gunshot wounds; in 16, collapse of buildings; in 23, road collisions; in 8, plane crashes; and in 18, blows, kicks, or falls. Of the 82 mandibular fractures, 78 were complete, 21 being single, 22 double, and 35 multiple and comminuted. Ten of these fractures had loss of bone requiring bone graft. The excessive violence of the trauma in many cases tended to produce a much more severe injury than was encountered in ordinary civil practice. There was a high incidence of unilateral and bilateral condylar fractures. Of the 37 cases of maxillary fracture, 20 were unilateral, 8 bilateral, 5 were "middle third facial" crush fractures, and 4 were partial alveolar.

Immediate Treatment

The initial treatment of the soft-tissue injury differed from that adopted in similar injuries in other parts of the body where radical excision of the damaged tissues and removal of all foreign bodies was essential at the earliest moment. The good blood supply of the facial tissues and jaws and their well-known resistance to infection allowed greater latitude, though early suture of the soft parts and immobilization of jaw fragments undoubtedly gave the best results. In the unit the plastic surgeon dealt with the facial injury, and the dental surgeon made impressions, localized fragments, and prepared and adjusted splints.

Within the first twelve hours facial injuries might be sutured with impunity, provided great care was taken to cleanse the wounds thoroughly with soap and water and saline and to remove (with a steel curette if necessary) all foreign bodies and dirt which might have been ground in. Non-viable pieces of bone only were removed, and extreme conservatism was practised in regard to pieces which had the slightest chance of survival. Excision of wounds was unnecessary except for removal of non-viable tissue or to make accurate suture of severely damaged skin edges possible. The mechanical possibility of wound suture largely depended on whether tissue had been lost. If the amount of lost tissue was such that undesirable tension was produced, and especially if the displacement of the fragments was perpetuated or increased, it should not be attempted. It was remarkable how well a facial wound, packed widely open with saline gauze, would heal in the absence of all tension. All compound injuries of the jaws associated with external wounds should be adequately drained at whatever time they were seen. Delay in healing was often due to inadequate initial drainage.

Fractures of the Mandible

The soft-tissue suture, when this was required, having been completed by the plastic surgeon, the dental surgeon took over, his aim being the permanent immobilization of the fragments and the clearing up of sepsis in the fracture lines. Mr. McIndoe discussed various methods of immobilization. The method of choice, for several reasons, was cast-metal cap splints—for example, they gave positive fixation and stable immobilization; they could be modified so as to be applicable to practically all except edentulous cases; and there were no wires to break or readjust.

To control sepsis the teeth in the fracture lines were removed, especially those with broken and septic roots, though where only one tooth remained on a fragment it should be retained as long as it was of value in immobilizing the fragment; also unerupted third molars lying in fracture lines were best left until sufficient consolidation had occurred to make removal safe. Careful irrigation of the fracture cavity and a rigid toilet of the mouth were essential if sepsis was to be prevented. Food must not be allowed to collect between the bone ends. During the period of immobilization, and particularly in comminuted fractures with perforating wounds, sequestra were extruded. If a purulent discharge persisted beyond six to eight weeks the fracture cavity should be gently curetted and any dead fragments of bone removed. In simple fractures the splints were removed after four to six weeks and the mandible tested for union; they were reapplied for a further four weeks if this was not sufficient.

Fractures of the Maxilla

As the degree and direction of maxillary fractures were directly related to the severity and direction of the blow producing them and not to muscle action, early disimpaction and immobilization of the fragments were essential. The responsibility for forcible manual reduction of these fractures rested with the plastic surgeon, who should be able to hand the case over to his dental colleague with the fragments repositioned and ready for splinting in normal dental occlusion. Bilateral maxillary fractures constituted the most serious problem, and in some of the conditions encountered it was of great importance that the fractures should be disimpacted at once, for if consolidation occurred replacement was extremely difficult. Immobilization depended on finding a point of resistance upon which to splint within the bony facial structure, or, if none was available, creating one by external means. Thus moderate displacements of the maxillary arch could, after replacement, be splinted to the lower teeth with full upper and lower cap splints. Elastic traction was of use in making minor adjustments in position. If the maxilla was very loose and the antral superstructure was intact, upward traction with a Kingsley type of splint and plaster head cap was advisable.

Complications and Sequels

A considerable number of severe compound fractures of the jaws, particularly those due to perforating missiles, resulted in obliteration of the buccal sulcus to such an extent that the satisfactory fitting of dentures was impossible. Almost all cases which had to be bone-grafted fell into this category. It became necessary then to deepen the upper or lower buccal sulci by dividing the adhesion between the lips and alveolar surfaces and to line the resultant cavity with a skin graft. A few cases of mandibular fractures, particularly the high condylar lesions involving one or both temporo-mandibular joints, developed trismus. In the early stages an exerciser was used to keep constant pressure against the temporal muscle pull and maintain a full range of movement. If this failed it was necessary to resect one or both condyles, including part of the mandibular neck, to form a false joint. The jaws were fixed together for one week, after which the exerciser was used to regain movement.

Of the cases treated 12% had been bone-grafted. In general a gap of 1 cm. uncrossed by periosteum and without intervening viable bone fragments would result in non-union. There was practically no limit to the size of the gap which could be satisfactorily grafted. The practice of the unit was to strive for occlusion with union wherever possible, but if good occlusion was not compatible with union because of bone loss, non-union with subsequent bone-grafting was willingly accepted. A bone graft was not inserted until four to six months had elapsed from the last signs of sepsis. During this time the fragments were splinted to each other by the rigid bar type of cap splint, or splinted to the upper teeth in the

more extensive unilateral losses. The iliac crest graft had entirely supplanted other methods. Bone from this source was tough, could be bent and shaped, was highly osteogenetic, and was easily obtained in amounts sufficient for the smallest or largest bone graft without disability to the patient. The grafts, after shaping, were wired accurately between the exposed fragments, using stainless steel ligatures. Union should be firm in four weeks, and movement could then be allowed.

TRANSFUSION OF BLOOD DERIVATIVES

At a meeting of the Section of Medicine of the Royal Society of Medicine on January 28, Sir MAURICE CASSIDY presiding, a discussion took place on the therapeutic value of transfusion of derivatives of blood.

Colonel LIONEL WHITBY said that it was desirable to recognize the limitations of blood derivatives, and also the fact that the exigencies of war were not necessarily to be copied in peacetime practice. The summoning of a blood donor was often highly inconvenient, while the conveniences of the blood bank were obvious, so that there was a temptation to lower the therapeutic ideal. The object of a given transfusion should always be clearly defined, because almost all derivatives of blood lacked one or more of the properties of fresh blood and had therefore a limited therapeutic value. As a general rule derivatives of blood were efficient for the purpose of the blood volume restoration essential to the treatment of secondary shock, but stored blood might be quite useless for oxygen-carrying capacity, though a good deal depended upon the age of the stored blood, and blood a few days old might be almost as good as fresh.

The order of preference of blood derivatives used for blood volume restoration had been experimentally evaluated as follows: citrated plasma, serum, haemoglobin-Ringer, gum saline, red cells in saline suspension, and isotonic saline and glucose. The clinical evaluation of the advantages of plasma over serum or vice versa had not yet been fully decided. A serum preparation, dry or fluid, was technically much easier than plasma. For blood volume restoration in secondary shock an innocuous protein fluid which was retained in the circulation was required. It was necessary not only to restore blood pressure but to maintain it, and the only satisfactory means of maintaining blood pressure was of a protein nature.

As for the transfusion of other substances, 25% haemoglobin-Ringer was quite efficient for restoring and maintaining blood volume, but it had the grave disadvantage that the haemoglobin was a foreign pigment and had to be excreted. Gum saline was reasonably efficient, but it had certain disadvantages, the most important being the difficulty of making one gum saline solution similar to another. As to the transfusion of glucose, this was subject to the same drawback as saline—namely, evanescence. Extensive experience had shown that, though citrated plasma was very satisfactory, it was an advantage to use a proportion of blood when the volume restoration was required to be large. In treating 100 air-raid casualties 165 pints of plasma had been used, the maximum administered in any one case being six pints. Rigors, mild and transient, were exhibited in only three cases. He added that the effect of the transfusion should be carefully controlled by serial blood-pressure observations as well as clinical judgment.

Experience in Air-raid Casualties

Dr. JANET VAUGHAN (with whose work on this subject Dr. Helen Brown was associated) described the results obtained at the North-West London Blood Supply Depot, where plasma, serum, and concentrated red cells had been analysed. The observations made under air-raid conditions were necessarily qualitative rather than quantitative, because the casualties were not often suitable for accurate controlled studies. If there appeared to be little variation in relative therapeutic value or toxicity of the derivatives, then other factors, important in wartime, such as ease of preparation, of storage, and of transport, had some title to be considered. Both filtered and unfiltered plasma with an approximate protein content of 4% to 5% had been available for clinical control, and reconstituted dried serum and filtered serum had also been tested, the latter with a protein content of 7%, while the protein of the former was dependent on the concentration at which it was given. On the question of relative toxicity of plasma and serum as opposed to stored blood, relatively large quantities of both had been used during the last four months, and there had been no report of a really serious reaction. With either filtered or unfiltered plasma only a very few cases of mild rigor and rise of temperature had occurred. In only a few cases had filtered serum been used; two of these cases showed a mild reaction (in one the serum was cold, and when it was warm no reaction was obtained).

Experience had led her to believe—although assessment was difficult—that plasma, serum, and blood were equally effective in the treatment of patients with "shock," by which she meant patients who had collapse associated usually with trauma, with a lowered body temperature, and a state of terror. As some degree of anaemia had frequently been found in air-raid casualties, it was probable that the best results would be obtained on the administration to such patients of both blood and protein fluid. In the case of burns, when haemoconcentration occurred plasma or serum was to be preferred to blood in the first twenty-four hours. Cases of burns were very likely to develop local oedema in the region, and on giving concentrated serum at that stage this local oedema vanished as by magic. In the late septic stages of burns fresh blood, so long as it was obtainable, was to be preferred to any of the derivatives.

No great difference in the dosage of blood, serum, or plasma had been noted. Dried serum had the additional advantages that it did not clot, was not readily infected, was uninfluenced by temperature, and had small bulk. If fibrinogen was found to be of importance in treatment, then it must be recognized that plasma was superior to serum, but at the moment from the practical standpoint serum was the preferable fluid. With regard to concentrated red cells, the type of cases which had benefited had been anaemia in elderly subjects requiring immediate operation, anaemia associated with sepsis, and aplastic anaemia. All the blood derivatives had proved their use, but more detailed studies were needed to assess their precise therapeutic value.

In a brief discussion Dr. DAVY said that although Dr. Vaughan had given reasons for preferring serum to plasma, from the point of view of the person who was running a blood bank the availability of plasma was a consideration. Dr. MAIZELS also said that while as a counsel of perfection it would be better to use serum, the practical usefulness of plasma in the case of blood banks must be remembered. It would be wrong to think that infection with plasma was of a serious character. It was almost unavoidable in some degree, but by careful precautions, using a separate outfit for each bottle, the infection rate in his own cases had been lowered to 2%. Dr. QUIST described two cases of burns sustained during the fire of London on December 29 which bore out the good results ascribed to concentrated serum. Dr. MOLLISON said that in giving a suspension of red cells it was a distinct advantage to have a count of more than 7,500,000.

Colonel WHITBY took up a remark made by Dr. Vaughan that 400 c.cm. of reconstituted blood serum was sufficient for the treatment of secondary shock. The treatment of secondary shock was an entirely individual matter. There must be large numbers of cases in which 400 c.cm. was sufficient reasonably to restore blood volume, but the only criterion of how much was required was to be determined by individual examination of the blood pressure or by other methods in particular cases. These average figures meant nothing; each case was an individual matter. Dr. JANET VAUGHAN said that she was sorry if she had given the impression that there was any automatic dosage for the treatment of persons with shock. The only guide was the patient's condition. The point that she had wished to make about dosage was that there seemed to be relatively little difference between the sort of dosage which was being used by a large number of casualty officers not all under the same direction. They were using approximately the same quantities of serum, plasma, and whole stored blood. But she agreed that each case must be judged on its needs.

Correspondence

Treatment of Scabies

SIR,—Dr. H. M. Berncastle's method of treating scabies (January 25, p. 135) is by no means original. Thomas Bateman, in his *Synopsis of Cutaneous Diseases*, first published in 1813, makes the following statement: "Among the remedies appropriated to the cure of Scabies, Sulphur has long been deemed, both by the vulgar and the erudite, to possess *specific* powers. The common people treated this disease with this substance alone, a century ago, administering it internally in milk and applying it externally in butter and Hog's-lard. In less violent degrees of Scabies, and in the purulent species affecting the hands and wrists, perhaps no improvement can be made upon this practice. The latter species, when it occurs in children, is often readily removed by the internal use of this medicine alone, or in combination with a neutral salt, independently of any external application."

Anthony Todd Thomson, in his *Practical Treatise on Diseases Affecting the Skin* published after his death in 1850, writes: "But Scabies is seldom treated by topical remedies only. Sulphur is usually administered internally at the same time, and, when strong objections to the use of the ointment exist, the disease may be cured solely by the internal administration of the specific. It is given in doses of half a drachm night and morning daily, either in milk, or, as the common people employ it, mixed with treacle in the form of an electuary. It undergoes a chemical change in the habit, combines with hydrogen, and is exhaled by the skin in the form of sulphurated hydrogen; a fact exemplified by the blackening of silver worn in the pockets of those taking it."

It must be noted, however, that neither Bateman nor Thomson believed that the acarus was the cause of the disease; the latter considers that: "Sulphur operated, either chemically in changing the nature of the poison which has caused and keeps up the disease: or by some specific action on the capillaries, preventing the formation of more of the poisonous secretion constituting the virus, whilst that already formed is thrown off by the skin." He adds as an afterthought: "There can be little doubt, however, that the insect is also destroyed during this process." How he arrived at this latter conclusion he does not state, and it is not clear that he ever obtained an acarus from any of his own cases, though he had been shown it by others. Bateman frankly admits that he had never found an acarus in any of his cases.

Ferdinand Hebra, the great Viennese dermatologist, who may well be called the founder of experimental dermatology, had no doubt as to the cause of scabies. He not only constantly demonstrated the presence of the acarus, but also experimentally produced the disease by placing acari on the skin and observed the development of the lesions. In his monumental work on *Skin Diseases* (English translation by New Sydenham Society) he writes: "Even when it was still contended that Scabies had its origin in a dyscrasia, all practitioners were agreed that, in order to cure it, it was necessary to use local applications. And yet till quite recent times it has been maintained that the external must be aided by internal treatment, in order to ensure radical cure of the disease and to prevent it being followed by any injurious consequences to the patient. But while this was the opinion of physicians, the quacks and 'old women' had more sense, and adopted a reasonable and simple treatment, by which they succeeded in gaining both credit and money, after their learned competitors had failed. If medical men in those days had but observed with unprejudiced eyes the favourable results which followed the use of popular remedies and cures for Scabies, they probably would have much sooner acquired correct notions concerning the nature and treatment of the disease."

Even though views as to the causation of scabies had changed, it is difficult to believe that a remedy—which was evidently at one time in constant use—would have been discarded if it had been as effective as Dr. Berncastle imagines. Scabies has increased very much during the last ten or twelve years and may increase still further as a result of war conditions. If this increase is to be stopped, efficient treatment is essential. Inefficient treatment may convert an active into a latent case, one in which the symptoms are relieved but the disease is not cured and remains infectious. It would therefore seem advisable to employ methods of proved efficacy rather than those in which it has not yet been possible to control the results experimentally.—I am, etc.,

London, W.1, January 27. A. M. H. GRAY.

Treatment of Wounds with Bipp

SIR,—Prof. R. J. Willan's letter (January 11, p. 62) urges me to write in support of the claim he gives to the late Prof. Rutherford Morison as the originator of a new principle in surgery. I was among those who began to practise treatment with bipp in the early days of the war in France, following Morison's technique, and later while serving as consulting surgeon to the Second Army I was able to observe many varieties of wound treatment and to see the early favourable results of hundreds of cases treated with bipp. As so often happens when new methods are introduced, failure to carry out the technique correctly—leaving large quantities of bipp in the wound—was often the cause of bad results.

At one time considerable controversy arose, chiefly because of occasional bad results and a certain amount of prejudice, between those working at the base and at the front as to the merits of bipp. The chief rival to bipp at that time was the Carrel-Dakin treatment. Good as this method was, it required considerably more after-attention than the bipp method and was not nearly so convenient for early transport. Both methods depended for success on the efficiency of the primary surgical treatment, and probably there was little to choose when this had been carried out *secundem artem*.

I think it may be claimed that bipp treatment was a, if not "the," progenitor of the vaseline pack, because it inaugurated a continuation of paraffin drainage (I am no advocate of primary suture as part of the technique when sepsis has already occurred), rest, fixation, and infrequent dressings, combined with an antiseptic base. It is difficult to know whether the gradual liberation of iodine was an added factor, though reasonable to suppose that it was, as Morison believed. At the present time this principle has been perfected with impregnated gauze pack and rigid plaster fixation (not necessarily closed). Whether the use of flavine or other dyes in the pack adds to the safety of the method remains uncertain. There is little doubt, however, that the local use of sulphanilamide combined with its internal administration adds considerably to the value of the up-to-date pack-fixation treatment of wounds and has produced results unobtainable in the last war.

Prof. Morison obtained astonishing results with bipp on cases with well-established infection, and it would be reasonable to give this method a re-trial in those late cases where established infection does not justify wound excision.

Since the last war, like Prof. Willan, I have employed bipp for the abdominal wall in cases of acute suppurative appendicitis, etc., before the peritoneum is opened, in a considerable number of cases, followed up by primary suture without drainage. It often happens that the wound in such cases tends after a varying interval to break down in varying degrees as the result of an infection of the muscle wall during the operation, a result which can often be avoided by a film of bipp over the wound surface. I have not the reference by me, but a series of these cases in which bipp was used was compared with a similar series in which bipp was not used by my chief assistant, Mr. (now Lieutenant-Colonel) D. Coyte, and the results, which were very favourable to bipp, were published, I think, in the *St. Bartholomew's Hospital Reports* some fifteen years ago.

Another valuable field for bipp is peri-anal suppuration (ischio-rectal abscess, fistula, etc.). Frequent dressings are avoided, pain eliminated, and healing accelerated. Although in the modern surgery of infection we are moving away from antiseptics and pinning our faith to chemotherapy, fixation, avoidance of dressings, and protection against ward infection from every source, I believe there is still a place for bipp, which has certain merits of an almost uncanny nature.—I am, etc.,

Jan. 18. C. GORDON WATSON.

Treatment of Burns

SIR,—I have never been satisfied with the treatment in general practice of burns and scalds. I realize the improvement brought about by the introduction of the tannic acid method, but I am not enamoured of it for a couple of reasons I need not dwell on now.

The following case may interest my colleagues. About two months ago I was called to attend a woman, 88 years of age, whose nightgown had caught fire on an electric heater. The burns extended from the middle third of the right thigh, up over her buttocks and up to the right breast and on to the front of chest. Practically the whole area was blistered, and in five places, each about the size of one's palm, the burn was deeper and the flesh blackened. She was so badly shocked that I had little hope of her recovery from this, and I had no hope of her surviving the accident. After the usual treatment for shock she rallied, and I decided to treat the burns with 2% gentian violet solution. (The *Practitioner* had just published an interesting article on this treatment.) I exposed a small area of the burn region and poured the solution over it, heating the solution beforehand to blood heat. This was allowed to dry and then covered with gamgee tissue. The rest of the burn was treated in a similar manner and the dressing carried on twice daily for ten days. The injured surface remained clean and healthy. I might mention here that I gave the patient 3 grammes of sulphapyridine by injection in the first twenty-four hours. She ran an uneventful course, and after ten days I changed to the following healing ointment:

R	Resorcin.	... gr. iij
	Adip. lanae	... ʒ ij
	Ung. zinc. oxid.	... ʒ ij
	Vaselin.	ad ʒ j

The deep burns required a few applications of copper sulphate. The patient has recovered completely and is going about as usual.—I am, etc.,

Bray, Co. Wicklow, Jan. 21. H. J. RAVERTY.

SIR,—May I supplement the appeal of Mr. Cohen (November 30, p. 754) for the continuation of the tannic acid regime in the treatment of burns? It is tragic that a method of treatment which has been approved should be condemned because of the appalling results shown by medical officers who have had no previous experience in the treatment of these cases. Apart from burns complicated by gunshot wounds, I have seen no conditions in wartime burns which were not well recognized in the teaching general hospitals. There, also, we not infrequently saw bad results from coagulation, due entirely to ignorance or criminal carelessness.

Many of us have already tested the alternative methods recommended, but abandoned them in favour of one of the modifications of the Davidson principle. When the war clouds loomed on the horizon, I, like others in teaching hospitals, reviewed the methods at our disposal, in consultation with medical, surgical, and pathologist colleagues. The conclusions were similar to those so ably set out by Mr. Cohen. Admittedly the coagulant varies with different surgeons, but in extensive injuries it is essential that coagulation should be rapid and "adequate," and these conditions are best fulfilled by some modification of the Bettman technique. If the face and hands alone are burned (the common distribution in Air Force casualties), speed is not so essential. In the former type of injury we are concerned primarily with saving life; in the latter the probable ultimate result is our first concern.

In some 300 cases of burns of the hands and fingers (many of them in children) I have never seen necrosis of the phalanges or disastrous crippling of the fingers which could be blamed on the tannic acid. The danger of the constricting effect of the tannic acid coagulum has been recognized for many years, and we should all appreciate that constant supervision is necessary. The danger of corneal ulceration and the possibility of ectropion resulting from burns around the eyes should be equally well known.

Every burn should have unremitting care and attention, and it is perhaps unfortunate that so many burns recover uneventfully in spite of lack of attention. This fact has led to an impression that the burn is cleansed and coagulated, and ten to fourteen days later the coagulum peels off and the patient is cured. When this routine is upset by toxaemia or sepsis it is thought to be "just bad luck." *Any* burn may "go wrong," and it is only by constant attention to all cases that improvement in results can be obtained. The use of the triple dye in itself will not lead to improved results. I abandoned this method as a routine, as I found the coagulum required even more attention than a tannic coagulum supplemented by dye. Saline baths also require time and care. If we admit that adequate supervision of these cases is impossible, then we should revert immediately to the pre-Davidson era, and admit defeat.

Although I am very much on Mr. Cohen's side, I disagree with him on one or two minor points. Like him I use a modified Bettman technique, but I do not coagulate burned eyelids and malar regions in every case. Superficial burns here heal well with saline compresses, or under 1% gentian violet. In the deeper burns early Thiersch grafting obviates the risk of ectropion. I consider that coagulation in this region is much more dangerous than coagulation of the fingers.

Secondly, the tannic acid–silver nitrate coagulation is rapid, but I have had to deal with sailors and airmen with extensive burns (40% to 60% of the body surface) who were too severely shocked to be satisfactorily dealt with in this manner. Several of these men suffered multiple gunshot wounds, and the need for speed was pressing. The face and body were tanned in the usual manner, while the limbs were rapidly bandaged with a gauze roll soaked in 20% tannic acid. If the shock was very severe, the patient was morphinized and the burned areas wrapped in gauze soaked in tannic acid, without preliminary cleansing. Twenty-four or thirty-six hours later the burns were cleansed and re-tanned, where necessary under gas-and-oxygen anaesthesia.

My final difference of opinion is on the distribution of patients throughout general wards. I prefer to segregate them in a ward by themselves, or at least to isolate them from "dirty" cases. This surely reduces the incidence of sepsis, and the staff of the burn ward become very enthusiastic and, I think, have a whole-time job.

I sincerely hope that others will voice their opinion in this controversy.—I am, etc.,

WALLACE M. DENNISON,
Major, R.A.M.C.

Dec. 4.

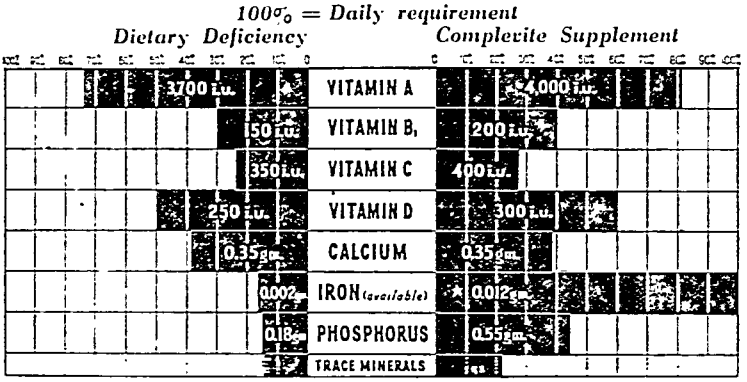
Cut Tendons

SIR,—The recent discussion on tendon injuries may give rise to unwarranted optimism regarding the flexor tendons among those who have little opportunity to see these cases. I have attempted a number of primary and secondary repairs by modern non-traumatic methods without benefiting a single patient, and have never heard of a case where a flexor tendon divided in its digital sheath has been restored to usefulness by suture. The plastic reconstructions described by the American surgeons are outside the range of all but a few specialists, and their value is still in doubt.

When flexor profundus is divided it should be left alone, as the finger is still useful. It usually retracts through the perforation in flexor sublimis, and cannot be retrieved without endangering the function of that tendon also. If both tendons are divided the hopeless prognosis should be told to the patient, and amputation considered in relation to economic and occupational conditions. If a tendon is partly divided little can be gained by inserting suture material, which only adds to the inevitable and crippling inflammatory reaction. Divided tendons not in synovial sheaths can be repaired satisfactorily by excision of the wound, the tendon ends, and all damaged tissue with primary suture.

I am sure that any surgeon who can produce case records in which suture of a flexor tendon in its digital sheath has led to useful voluntary movement at the corresponding interphalangeal joint will soon excite considerable interest in his methods. In the hands of most of us the prognosis is quite hopeless.—I am, etc.,

Bradford, Jan. 25. J. CLAPHAM COATES.



A **Single** *Supplement for* **Multiple** *Deficiencies*

Patients whose illnesses have been either produced or influenced by dietary deficiencies present certain difficulties in treatment.

While a single deficiency, such as that of Vitamin A or of iron, may be sufficiently outstanding to call for immediate treatment, it is practically certain that a diet with one such prominent defect will also have others which will retard recovery.

It is, therefore, of some benefit to the patient to prescribe a supplement to correct only the one deficiency, but much greater benefit can be given by choosing a preparation which will compensate for the multiple deficiencies found in so many diets. The degree and the rate of recovery may both be influenced.

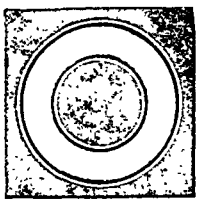
Complevite is the only dietary supplement which contains the essential vitamins and mineral salts in a wide enough range and in sufficient amounts to bring poor diets up to the levels believed to be fully adequate Containing vitamins A and D, B1 and C, together with iron, calcium and the trace minerals, it provides, in the one preparation, all that the physician could look for in a dietary supplement.

* The iron in Complevite exceeds the calculated deficiency expressed to combat the nutritional anaemia so common in children and women of child-bearing age

COMPLEVITE

The first **Complete** Vitamin and Mineral Supplement *making good the actual deficiencies in daily diet disclosed by recent surveys*

Full particulars and complimentary bottle of tablets gladly sent to medical men. Vitamins Ltd. (Dept. B.C.K.), 23 Upper Mall, W.6



FERTILOL *Clinical grounds for considering its administration*

Frequent use is now made of whole wheat germ oil (as in Fertilol) in the treatment of habitual abortion and sterility of dietary origin.

Other conditions in which it is now being used are primary muscular dystrophy, amyotrophic lateral sclerosis, after poliomyelitis and in rarer cases, such as amyotonia congenita.

Whole wheat germ oil has been available since 1934 as Fertilol, which is a highly active natural and *stable* source of vitamin E, together with the other naturally occurring factors of wheat germ oil.

Complimentary box of capsules on request. Vitamins Ltd. (Dept. B.F.D.), 23, Upper Mall, W.6.

prophylaxis of Surgical Shock

". . . The results in 12 consecutive instances in patients with chronic diseases in whom such operative procedures were performed as resection of colon or stomach, thorocoplasty and the like.

"None of these patients had any evidence of Addison's syndrome as determined by serum sodium, potassium and haematocrit determinations.

"In all instances the patients were strikingly benefited; there was no objective evidence of shock, blood pressure was maintained or elevated from 10 to 30 mm., the temperature in general returned to normal within 24 to 48 hours, post-operative exhaustion and toxaemia were definitely lessened, complications did not occur and operative recovery appeared, to the surgeons concerned, to be more rapid than in their preceding surgical experience with similar conditions in our hospital.

"On the chest service the procedure has been adopted as a routine."

Agents in countries abroad and throughout the British Empire

SIR,—Since Mr. A. Wilfred Adams gave a good prognosis for tendon suture (November 30, p. 765) many diverse opinions have been expressed, many of them pessimistic. Dr. T. B. Jobson's letter (January 25, p. 138) again brings up the subject, stressing accurate suture, asepsis, and care not to injure the sheath unnecessarily.

There remains one other means of preventing adhesion of the tendon—the use of cellophane. After suture has been accomplished by fine linen thread, the line of suture is surrounded by cellophane, which is easily sterilized. A small portion is placed in position to form a minute tunnel, and its naturally gummy surface when wet allows it to adhere to itself, so that rarely even a stitch is required. After adequate immobilization, followed by active and not passive movement, the results in the few cases in which I have used the method, which is not original, are excellent.—I am, etc.,

Upper Deal, Kent; Jan. 29. C. G. S. MILNE.

Amniotic Membrane for Cerebral Adhesions

SIR,—In connexion with Dr. Wilder Penfield's statement (November 16, 1940, p. 668) that unboiled amniotic membrane is unsafe to use by reason of its fatty content we desire to record the following observations.

Both the boiled and unboiled membranes prepared by us according to Dr. Penfield's instructions have a large and almost equal fat content. This fat manifests itself as intracellular clusters of fatty droplets probably representing fatty degeneration. The only apparent change effected by boiling is to transform the membrane to an extremely puckered, shrunken, and friable state. The fat is not removed to any considerable extent by boiling as recommended. In view of these findings we feel that any difference in results observed by Dr. Penfield from the use of the boiled and unboiled membrane should not be attributed to alteration of the fatty content of the membrane. Probably some other factor has been responsible.

Fat can readily be removed from amniotic membrane by the use of fat solvents, and the membrane can be sterilized and maintained in good condition as follows: (1) amnion is carefully separated from chorion and put into acetone for fifteen hours; (2) rinsed in 70% methylated spirit in water to remove acetone, and stretched upon rough towelling to dry for twenty-four hours; (3) cut into convenient pieces and all discoloured or stained portions rejected; put into ether for a further twelve hours; (4) wash the etherized amnion through 70% spirit (as in step 2), and again dry upon rough towels for twenty-four hours.

To sterilize: Sterilization is effected by interleaving each sheet of prepared membrane with grey filter paper. A board (half-inch-thick teak or cedar for minimum warping) is placed on top and bottom of the pile of sheets, and the whole is wrapped in a cloth and autoclaved for ten minutes at 5 lb. pressure, followed by vacuum 5 lb. for another ten minutes.

Our observations, however, do not enable us to state whether the effective removal of fat in this way is of practical value for the purpose in view.—I am, etc.,

Royal Infirmary, Edinburgh, Jan. 19. L. J. LE VANN.

Spinal Anaesthesia

SIR,—In his article, "The Surgery at No. 3 General Hospital" (December 7, p. 794), Major Rex Binning, referring to spinal anaesthesia and advocating the lateral approach, states: "By avoiding the tough intraspinous ligament one is less liable to bend a fine needle and it eliminates the need for a Sise introducer." This sentence raises a number of points connected with the technique of spinal anaesthesia, and I hope to substantiate my claim that the midline approach is at least as satisfactory as the lateral, if not, indeed, more so. An advantage of the midline method is the absence of lateral angle of introduction. The distance from skin surface to dura mater certainly varies in different individuals, and this in itself can upset calculations of angles of introduction.

The tough intraspinous ligament and Sise introducer are both easily overcome by the following slight addition to the technique. After preliminary local anaesthesia of skin and area of track with the agent to be used, approximately two-thirds of the actual track is prepared by the insertion of a Record syringe needle of the same diameter as, and half the length of, the lumbar puncture needle to be used. When this is withdrawn a hole will remain, and it is a simple matter to direct the lumbar puncture needle along it and then through into the spinal canal. Actually, in practice, the skin itself often forms a tough barrier to the lumbar puncture needle, a problem also solved by the sharper and shorter preliminary needle.—I am, etc.,

H. L. ROGERSON.
Major, R.A.M.C.

Mental Health Administration in the Provinces

SIR,—Your leading article on "Hospital Administration in the L.C.C." (January 11, p. 56) is very timely. The fact that some of the mental hospitals are now being used partly as general hospitals makes the present time particularly favourable for the suggested fusion. Such fusion is an urgent necessity in the Provinces. In many provincial counties one finds a complete lack of co-operation between the municipal general hospital, the mental hospital, and the mental defective colony, each is run by a separate committee.

The recent report of the B.M.A. Committee on Mental Health includes a model scheme for the treatment of mental illness, and there is a recommendation that a Central Advisory Committee should be set up in each area to devise a co-ordinated plan for that area. (These committees would be composed of representatives of voluntary hospitals, medical schools, and voluntary organizations dealing with mental health and mental defect, and educational and health representatives from public authorities.) This appears to be an excellent recommendation, especially as the term "area" obviously implies a grouping together, where desirable, of several counties; in fact, it foreshadows the regionalization of the mental health services.

Now this whole question of the replanning of the hospital system of the country on a regional basis has just been brought sharply into prominence by the letter from the Minister of Health to the Chairman of the Nuffield Trust which was published in the *Journal* of January 18; and the *Times*, in a leading article, commenting on the work of the Nuffield Provincial Hospitals Trust which Lord Nuffield founded to promote a general scheme of regionalization of the hospital service, points out that full participation by the public health authorities was one of the binding conditions.

From these considerations it seems quite clear that before the local mental health services are in a position to set up influential central advisory committees or to take part in any useful regionalization scheme, there must be full co-operation with the local public health authorities, and to this end amalgamation of public health and mental hospital committees is the first necessity. Not until this is done will it be at all easy to form central advisory committees which will carry any weight. And as this need for co-operation is so much greater in the Provinces let them "go to it."—I am, etc.,

Warwick, Jan. 20. FRANCIS PILKINGTON.

Convulsion Therapy in the Out-patient Department

SIR,—It is more than unfortunate that when the nation is likely to make calls on psychiatry which it may find difficult to meet owing to the limited number of trained psychiatrists available, the discussion on convulsion therapy is degenerating into an undignified wrangle. It is unhappily a fact that the practice of psychiatry in Britain is carried out in two compartments (or in three if we include mental deficiency). Much progress has been made in recent years in all branches, and while, on the one hand, it is foolish and incorrect to state that on admission to the mental hospital the mental disorder is necessarily far advanced and that in a few weeks the "asylum psychosis" (whatever that is) has been added to the original disorder, on the other hand the suggestion that a psychiatrist of recognized standing may never have known what an advanced psychotic is like is unseemly if no worse.

Experience of both classes of patients shows that for the most part the psychoneurotics respond to psychotherapy in an

out-patient clinic, while the psychotic, even if a very early case, reacts best to in-patient treatment in a hospital where proper classification and other "progressive" methods are available.

There are exceptions in both groups, and as new methods of treatment appear—electrically induced convulsions may prove to be one such—this generalization may not indefinitely hold good. While it exists, however, many psychiatrists, possibly the majority, tend to see one or other rather than both classes of patient. Each may thus be in a position to speak with authority as regards his own sphere, but we have a right to expect at least moderation when voicing opinions concerning the position of others.—I am, etc.,

W. J. T. KIMBER,
Jan. 29. Medical Director, Hill End Hospital and Clinic.

Bromide Therapy and Intoxication

SIR,—I am sorry that it should have become necessary for Dr. Francis Pilkington (January 4, p. 10) to have written such a lurid and depressing account of bromide intoxication. As he says, bromides are some of the most valuable drugs to be used in wartime, and I am surprised how often I find patients apprehensive of taking them. They seem to have no difficulty in swallowing those "beastly barbiturates"—made in Germany—though we have been warned often enough of their dangers.

It is remarkable how confidently, and as a matter of course, sisters at nursing homes ask: "And what shall she have to-night, doctor?" usually meaning a tablet with a name ending in "l." On the other hand, bromide is so useful; there is no need to give large doses, or even give continuous doses. Ten or fifteen grains given occasionally is often quite enough to soothe an active imagination. Bromides quieten thoughts, and a dose taken by a normal individual will give a day or two's respite to an imagination becoming too vivid. The patient soon learns to know when he wants another help to steady him. Of course, we all know this, but we did not know the terrible effects of an overdose or intoxication, and I have not seen a case in thirty years of practice.—I am, etc.,

Mortehoe, Devon, Jan. 25. H. M. RAVEN.

Acute Bronchiolitis in Children

SIR,—In their article on "Acute Bronchiolitis in Children" (January 25, p. 107) Drs. Douglas Hubble and G. R. Osborn stress the importance of obstructive dyspnoea. Although this disease does not often come the way of the thoracic surgeon, I have sometimes diagnosed such a spreading bronchial infection as an early complication of lobectomy for bronchiectasis. As far as such experience will allow, I fully endorse the treatment they recommend.

I am particularly interested in the question of bronchoscopic drainage. No amount of bronchial suction could be expected to aspirate tenacious plugs from the bronchioles, and if it could be ascertained that this was the only lesion, bronchoscopy would seem to be contraindicated. It may happen, however, that other factors are contributing to the dyspnoea, and of these the most important are secretion in the main bronchi, swelling of inflamed bronchial mucosa, enlargement of hilar glands, possibly some bronchial spasm, and also that unexplained phenomenon of a greatly reduced cough reflex. As Chevalier Jackson says in the quotation used: "The cough reflex may be entirely absent." Where these crippling factors are present to prevent lung drainage, the most dramatic relief may be obtained by bronchoscopic aspiration and spraying of the mucosa with a solution of decicaine and adrenaline. A discussion on the ways in which bronchoscopy helps would be out of place here, but I am sure that the air let in is as important as the secretion removed.

It is difficult to persuade a physician that a child who is in the last stages of respiratory failure would benefit from what is regarded as the suffocating process of bronchoscopy. One of the disappointments of the treatment is that in a very severe infection the obstructive agents may return within a few hours.

In one small boy of 9 years whom I treated in consultation with Mr. G. S. Seed the infection progressed to extreme respiratory obstruction in twelve hours from the onset of the first symptom. In spite of deep cyanosis, straining chest, and moist sounds over both sides, there was no cough. At bronchoscopy I found a reddened larynx and trachea, a deeply congested and broadened carina, and both main bronchi still further occluded by thick blood-stained secretion. When the suction tube touched the carina, coughing started and much thick secretion was aspirated. The effect of bronchoscopy was just as dramatic as tracheotomy in laryngeal obstruction. The child was immediately at peace. Obstruction recurred again an hour later and coughing was again absent. As bronchoscopy was obviously not going to be possible every hour, a tracheotomy was performed. A feather was passed down to the bifurcation of the trachea every half hour. This stimulated the cough and caused the expulsion of secretion. The child recovered completely in three days. To-day I should leave a bronchial catheter in place after bronchoscopy and so avoid a tracheotomy.—I am, etc.,

Leeds, Jan. 27. P. R. ALLISON.

SIR,—Drs. Douglas Hubble and G. R. Osborn in their article on acute bronchiolitis (January 25, p. 107) have drawn attention to the importance of this condition from the clinical point of view, but it is also of medico-legal importance. Sudden death from capillary bronchitis may take place in infants without previous symptoms sufficient to suggest serious illness. Death often takes place during the night, and should this occur while the child is in bed with its parents there is a risk that death may be attributed to overlaying, as the post-mortem appearances are those of death from asphyxia and the condition of the lungs may be overlooked unless a careful examination is made. In these cases the parents usually state that the child and often the whole family had suffered from a catarrhal cold, and a common and curious feature in the history is that the baby is believed to have recovered or at least to have passed the acute stage of the catarrhal illness when death occurs.—I am, etc.,

Wakefield, Jan. 28. P. L. SUTHERLAND.

Epidemic Influenza

SIR,—While appreciating Major C. H. Stuart-Harris's plea (January 18, p. 96) for patience with the research workers in elucidating the cause or causes of influenza one feels, as a clinician, that it is possible, once any virus is discovered, to approach the problem from a biased point of view so that, instead of seeking a cause, there is a tendency to seek only that virus of which one knows.

If, as Major Stuart-Harris states, he is unable to distinguish on occasion clinically at the bedside those cases which yield, for example, virus A from those which do not, then surely it is reasonable to suggest that none of these cases is due to virus A but to some other as yet undiscovered cause, be it virus or otherwise, rather than that 30% should be ascribed to virus A and the other 70% to the unknown infection.

You, sir, have suggested something of the sort in one of your leaders of last year, and one feels that such an approach is more likely to lead to the ultimate solution of the problem.—I am, etc.,

Highgate, N.6, Jan. 25. W. LEES TEMPLETON.

Sunlight Treatment

SIR,—In his excellent letter (January 18, p. 97) Dr. F. Howard Humphris ignores one of the most important actions of actinotherapy—the tonic action of general irradiation with a good strong erythema-producing dose. Presumably, in common with myself; there are practitioners who possess mercury vapour lamps, and who have experimented upon themselves until they have ascertained the most effective dosage: some of them, too, maybe love the sunlight and have learned how long to bask in it. Theirs are the opinions I should rather like on the matter of correct dosages.

Personally I find that my optimum dose is that producing a bright erythema, which appears within two hours, reaches its maximum in six to eight hours, and has not completely disappeared in thirty-six hours, and which leaves the skin slightly more pigmented than it was before. Desquamation is apparent in four to six days' time. In length of time such an exposure

is between two and two and a half times as long as the "minimal erythema dose." The effect of the bigger dose is to produce a feeling of well-being and renewed energy—a sort of "I-don't-know-what's-the-matter-with-me-I-feel-so-grand" feeling. Appetite is sharpened, and if bedtime supervenes rapid and deep sleep is enjoyed. A single dose relieves asthmatic attacks. Repeated exposures prolong the tonic effect, grant varying periods of immunity from asthmatic attacks (*British Medical Journal*, January 4, 1936), and enable convalescent and debilitated children to regain their lost body weight more than twice as fast as their controls (*Brit. J. phys. Med.* October, 1935).

It may be of interest to record the signs and symptoms that obtained (and were noted down at the time) on the five occasions when I have deliberately incurred over-exposure to ultra-violet light. These exposures were from twice to four times my "normal" dose; further than that I never dared go. At the time and for an hour afterwards there is nothing to warn one of what is coming. Within two hours the skin is "burning" too much to be comfortable. Within six hours the skin is exquisitely tender, the tongue is white-furred, there are headache, nausea, irritability, terrible depression (almost suicidal in intensity), and a positive craving for sleep, which becomes an obsession, and one can think of nothing except bedtime. Within twelve hours there is most offensive diarrhoea, after which the toxic symptoms rapidly disappear. Desquamation begins within twenty-four hours; large sheets flake off revealing "new skin" still erythematous. The last overdose I took deliberately was within five hours of a Turkish bath, at which all the superficial dead skin had been massaged away. On this occasion the toxic symptoms were excessive, tachycardia was suffered for three days, but there was no desquamation. The same symptom-complex obtained with two of my earlier patients to whom I inadvertently gave overdoses. A third patient (an asthmatic) had in addition delirium, painful swollen joints, and oedema of the eyelids—all suggestive of serum-sickness.

The effects of over-exposure appear to be transient, as with most other forms of intoxication. Latent septic foci, however, will sometimes light up, and it is said to be dangerous where active tuberculosis of the lung tissue is present. But is not the minimal erythema dose rather feeble? I am sure that our homoeopathic colleagues do not prescribe flashlight baths.—I am, etc.,

Vale Royal, Cheshire, Jan. 22. GEORGE DAY.

SIR,—I am sorry that Dr. F. Howard Humphris suggests (January 18, p. 97) that my letter (December 21, p. 883) decries actinotherapy and the mercury vapour lamp. I did not intend to do this. The observations he has made are of interest, as I know that they are based upon many years of clinical practice.

Without entering a long discussion on the energy of sources of light, expressed in physical terms—that is, ergs per sq. cm. per sec.—the various types of quartz mercury vapour lamps generally used in actinotherapy are relatively "cold" sources of light emitting a high intensity of ultra-violet rays which have powerful erythema-producing action. Other sources of light are more suitable when infra-red luminous or the longer wave-lengths of ultra-violet rays are prescribed for light therapy. In actual clinical practice the quartz mercury vapour lamp is most suitable for production of erythema reaction of the normal skin, and can be employed for general light therapy or local intensive counter-irritation therapy. Dosage needs supervision and control. I have advocated a technique of dosage which I have called "short-ray therapy"; unfortunately an error in printing inserted "short-wave therapy"; this needs no further comment.

By this method of treatment the minimal erythema-producing dose of rays of light is applied to an area of skin 12 in. by 12 in. An interval of ten to twelve days is allowed to elapse between the time when any of the selected skin areas are again irradiated. The advantages of this method of treatment are: (1) The dosage is accurate and can be correctly repeated by others. (2) Laboratory research supports this technique, for the optimum response of the bactericidal power of the blood will follow such irradiation. The exposure of large areas of skin will reduce the haemobactericidal power. (3) The skin is kept in a constant light-sensitive state. Immunity and resistance to erythema reaction of ultra-violet rays will follow thickening of the epidermal cells and hyperplasia caused by repeated weak and suberythema doses of ultra-violet rays. The penetration of the short wave-lengths are arrested. (4) The dangers of "overdosage" are prevented; these may occur when wide areas of skin are irradiated. (5) Suberythema and weak doses may be insufficient and of no therapeutic value, as the biological reactions of ultra-violet rays follow an "all or nothing" law.

There is little doubt that the longer wave-lengths also have therapeutic value; the observations made by Kovacs are well established, but if the high-pressure quartz mercury vapour lamp is to be used for this purpose it is necessary to screen or weaken the short wave-lengths of ultra-violet rays as long exposures are needed. Other lamps are more suitable for this purpose. The quartz mercury vapour lamp is a valuable agent for the treatment of disease and the maintenance of good health. Its use is most suitable in hospital, in private practice, and in industry, but the best results will follow correct supervision of apparatus, personnel, and dosage. Caution is needed when such lamps are installed in factories, the home, and elsewhere.—I am, etc.,

London, W.1, Jan. 27. ALBERT EIDINOW.

Effect of Morphine after Cholecystectomy

SIR,—A paragraph in Mr. Michael J. Smyth's article on exploration of the common bile duct for stone (January 25, p. 111), describing recent work on the action of different drugs on the sphincter of Oddi, explains to me a long-standing puzzle, and brings forward a point that may be of some practical importance at this time. Ever since a cholecystectomy many years ago a patient has shown what I wrongly supposed to be an idiosyncrasy towards morphine and its derivatives, even the tiny dose of codeine in a veganin tablet causing severe pain, now for the first time easily understood. There must be in the country a fair number of people without gall-bladders, who are potential air-raid casualties and to whom, if they become casualties, a full dose of morphine will probably be administered by a doctor who knows nothing of their medical history. One supposes that, far from relieving their pain and shock, this may increase it.

It is clearly impossible to obviate this risk completely, but I have given to my patient a note as follows to keep in the cover of her identity card.

IMPORTANT NOTE

A cholecystectomy has been performed. Morphine in *any form* causes spasm of the sphincter of Oddi with severe pain.

If morphine has been given or is absolutely necessary pain due to it can be relieved by

Inhalation of capsule of amyl nitrite *or* glyceryl trinitrate, gr. 1/100.

I have advised the patient to carry one or two amyl nitrite capsules with her.—I am, etc.,

North Shields, Jan. 27. J. B. WILLIAMSON.

The British Drug Industry

SIR,—In an article under the title "Rationalization of the British Drug Industry" in your issue of December 21, 1940, you take editorial responsibility for opinions which we submit are unjustified by the facts of the case. The official character of your journal makes it necessary for the Association of British Chemical Manufacturers to indicate to your readers certain of these facts. We therefore ask your courtesy in giving us space for this purpose and for making explanations which may help to remove the misconceptions to which your article has given rise.

The drug industry, like others born under a British system of free competition, is composed of a number of units in course of development. These are not, however, as you state, crowding each other out. On the contrary, through our Association, they are working closely together, and, contrary to your assertion, they have done so increasingly during the past year, though we readily admit that a still greater degree of co-ordination is desired by many of our members.

In addition to maintaining their own research departments, many British firms do also in various ways regularly lend considerable aid to research work carried out in the laboratories of universities and medical schools, and the suggestion

that they make no contribution whatever to such work stands in need of revision.

We acknowledge that greater unity in the naming of new drugs is desirable. Indeed, with this end in view, it was the Association of British Chemical Manufacturers who in 1939 first sought the help of the British Pharmacopoeia Commission in giving names for drugs formerly not made in this country that were known by registered trade names of foreign origin. These pharmacopoeial names are, with few exceptions, now used generally by members of the Association of British Chemical Manufacturers, although frequently in addition to their own registered trade marks. The purpose of the latter, however, is not to disguise the nature of the drug, but to identify it as the product of a particular manufacturer.

Your statement that it is due to the initiative and drive of the Medical Research Council that the drugs in the Addendum have been so quickly made available in this country also needs correction. Long before the war the British drug manufacturers took the initiative in asking for medical advice as to what drugs not already made here were to be considered as really essential to the medical profession. The Medical Research Council gave this advice, but it is due to the initiative and drive of the manufacturers and to the fact that they had previously established strong research and production departments that these drugs in the Addendum, as well as many others, have quickly been made available to the medical profession in a state of purity and in adequate amounts by the members of our Association.—We are, etc.,

THE ASSOCIATION OF BRITISH CHEMICAL MANUFACTURERS.
166, Piccadilly, London, W., Jan. 30.

The B.M.A. and Medical War Issues

SIR,—The *Journal* of January 4 contains a letter from Dr. Margaret Lowenfeld containing the following paragraph: "As a profession we are responsible to the people for their health. Is it not time we roused ourselves and as a body saw to it either that the Central Government makes use of those powers we have delegated to it or that by other and more direct means this objective is gained? *We have in the B.M.A. the necessary instrument to collect information, disseminate it, and see that pressure is brought to bear on the authorities. Let us take responsibility for our part of the war and 'go to it.'*" (The italics are mine.) In the same number of the *Journal* is a report of the last Council meeting, at which I made (not for the first time) similar remarks.

At the moment there is one important issue about which the Association is in a position to collect information and bring pressure to bear on the authorities so that the requisite action may be taken—and that is the medical aspect of the invasion we have been told by the Prime Minister to expect.

We have been told to stay put in the event of invasion. We know that the unprotected population flying from the intense aerial bombardment contributed in no small measure to the defeat of France. Does our experience in the bombed cities lead us to suppose that the refugee population in the reception areas will stay put in the event of an intense bombardment unless there is some reasonable protection? However high may be the morale of the civilian population in reception areas, we must consider the possibility that, in the face of the kind of attack we are expecting, they will try to escape by dispersing throughout the countryside. Leaving out all military considerations, have full medical preparations been made to deal with the disruption caused by this dispersal? Such a dispersal may well give rise to a spate of epidemics, and, apart from this, it will entail serious effects on the mental and physical welfare of the future generation.

A question that has been asked me more and more of late by doctors in my area is, "What are we expected to do in the event of invasion?" They want to be prepared for their duties, and so far as is possible in advance. Has the Association taken this matter up with the proper Departments? Is it decided which doctors should remain? Has the treatment of casualties in the civil population or in the Home Guard in the event of invasion been considered? If there is information on these points, is it not important that it should be disseminated as soon as possible?

The medical risks of a dispersal of the population in the event of invasion would be to a large extent lessened if there were adequate protection for the civil population in the reception areas of the country. Although such protection is primarily a military matter, it has a vital bearing on the medical aspect and is therefore one on which the Association should make its voice heard. In this connexion it is a matter for regret that the Association has not taken an active interest in the construction of shelters. Here again the questions of security against bombs and security against disease are closely linked, and if we are to envisage a long war it is still not too late for the Association to take this matter up.

In the report of the last Council meeting in the *Journal* of January 4 there is a reference by a member of the Council to the use of the *Journal* and the futility of ordinary committee methods. I agree that ordinary committee methods are futile at a time like this and believe that the columns of a weekly journal have the disadvantage that information in it does not lead to speedy action. The present machinery of the Association is adapted for the single purpose of obtaining personnel for the Forces and not for that of dealing quickly with day-to-day problems. What machinery is there for seeing that speedy action may be taken on vital matters? I would suggest that there is none, and also that it is still not too late for us to modify our organization so that we can more promptly meet the urgent needs of the moment. Relevant to this matter is the following quotation from an article in the *Sunday Times*, in which it was stated that the recent fire of London "revealed certain facets in the English character—a certain inability of the unimaginative official mind to prepare sufficiently in advance against the anticipated but unexperienced."

Let us, therefore, form a small body open to receive suggestions whose watchwords will be "speed" and "action," a body to prepare adequately in advance against the anticipated, so that it will no longer be possible to level against the Association that accusation—"too slow" or "too late."

Finally, may I say that a draft of this letter was shown to the Chairman of the Council before publication.—I am, etc.,

Birmingham, Jan. 31. S. WAND.

Medical Planning Commission

SIR,—The almost simultaneous publication of Sir John Orr's recent address (*Journal*, January 18, p. 73) and the details of the Medical Planning Commission (*Supplement*, January 4, p. 1) is indeed a blessing, for the former has given you, Sir, an opportunity to criticize it in the same spirit which has animated the minds of those who are responsible for the formation of the latter.

While there can be no quarrel with the essential medical points raised in Sir John's address, there is, as already evidenced by your public correspondence, a great deal of dismay and dissatisfaction with the manner in which the Medical Planning Commission has been constituted and the qualifications of its personnel to consider contemporary medical problems of fundamental importance, and your leading article (p. 91) on Sir John's address may swell the dissatisfaction, for it does not indicate that one of the main points raised in this address has received that wider and more intelligent consideration that is its due.

In the first place medicine of the future must be closely bound up with politics, and the sooner that fact is realized by the profession the sooner will we get a really intelligent survey of the problems which concern us. In the second place politics in the past has inevitably meant party politics, but it need not so remain in regard to medical matters if the profession can convince the public in the meantime that it has set its own house in order and is able to produce a cast-iron case for reform in practically every branch of its work. If the profession can produce such overwhelming evidence, as indeed it can and must, no political party would dare oppose or question such evidence, and the result would be a general acceptance by all political parties of this evidence.

How, then, must the profession proceed to make such a possibility a reality? The answer is simple enough to any unbiased mind—namely, the setting up of a commission composed of men and women who have practical experience of the many and complex problems which must figure in its terms of reference; and how extensive these terms of reference must be I hope to indicate at a later date. The reason for the discontent in regard to the present Medical Planning Com-

mission is due to the fact that the personnel has not been chosen with any real comprehension of the issues at stake, and until such a commission is appointed any findings of a commission with such obvious limitations as the present Medical Planning Commission, as constituted, will not carry the weight or authority of the profession, and will have the further unfortunate effect of misleading and puzzling politicians and public alike.—I am, etc.,

London, S.W.1, Jan. 28. R. PROSPER LISTON.

SIR,—While probably all are agreed upon the necessity for action the Medical Planning Commission as proposed has so many hostile critics that it would be wise to consider whether a better scheme might not be devised. It is clear that most of the criticism is caused by the fear that one interest or another will not receive due consideration; another ground of objection is that younger members of the profession are not adequately represented. It must be admitted that the findings of so large a body must depend on the votes of the majority, and as a consequence points of importance to a relatively small section may, if not presented with sufficient force and logic, be lost sight of, especially as an unbiased and judicial attitude cannot be expected from a body of men so many of whom have been appointed to represent sectional interests.

I suggest that a better method would be to appoint a small body, say six members, half from general practice and half from consultants and specialists, chosen only for their ability to form an impartial opinion and with a reputation for sound judgment, together with a chairman from outside the profession, perhaps a legal authority who would at the same time view the problems from the point of view of the general public, the patients. Witnesses, who would be chosen to represent all sections of the profession and all aspects of the problem, would give evidence before this commission. In due course a report would be prepared which might be expected to be impartial and comprehensive.

Such a small commission might be appointed by the Medical Planning Commission as at present constituted and the report when prepared would be presented to them. Later the report and their observations upon it would be made public for wider criticism, and the Commission might then formulate a scheme to be put into practice at the appropriate time with the whole weight of the profession behind it.—I am, etc.,

Buxton, Feb. 1. CHARLES W. BUCKLEY.

SIR,—Every right-minded practitioner will agree with the letter of Dr. Alfred Cox (January 11, p. 61) in commending the Association's initiative in setting up the Medical Planning Commission. The constitution of the Commission, however, is causing considerable misgiving, although, of course, no possible exception could be taken to any individual member. It seems probable that 90% would be a more correct estimate of the proportion of the profession made up by general practitioners than the 80% of Dr. H. Dundas McCall (January 25, p. 132). On the Commission there are only eighteen members whom the most elastic standard of classification could describe as general practitioners, while there are twenty-nine consulting surgeons and physicians, seven other specialists, and three deans of medical schools.

Many will be rendered still more uneasy by the fact that they agree with Mr. P. L. Giuseppi's vision (January 18, p. 97) of a full-time medical service. But among general practitioners there is a growing feeling that their interests, which they believe in health matters to coincide with those of the nation, are not likely to be best sustained by the hands of consultants. It is not many years since many of our eminent colleagues were constantly assuring us that the family doctor was the backbone of the profession. But we do not forget that at the same time agreement was reached with a Ministry of Health scheme which had the effect of driving the thin end of the wedge between the general practitioner and the practice of midwifery, and which may ultimately lead to the complete disappearance of that part of his practice. And in spite of hopeful words, encroachments upon general practice grow daily.

If a full-time service should ever come into being, the importance of the part which the Association can play in its delivery cannot be exaggerated. But it can only play such a part if it can command the solid confidence and support of all ranks of the profession. I submit, Sir, that it is urgent that such a pronouncement shall be made at once as shall silence once and for all suspicions of the kind expressed above.—I am, etc.,

Croydon, Jan. 23. J. NEWTON HUDSON.

Medicine in a Changing World

SIR,—Sir John Orr in his lecture on trends in nutrition expresses his conviction that what may be termed the creation and preservation of "positive" health of body and mind of the community is the primary duty of the medical profession. Naturally it should accompany or precede the reorganization of the preventive and curative medical services in the more limited sense of these terms.

Sir John Orr's address shows good "visibility" and comprehensiveness and is medical planning on a national basis, the only complete and lasting form of planning, and is refreshing. In it he claims that doctors should take their rightful place as citizens in the "New World Order," of which we hear much, and he makes certain recommendations to bring this about. He refers to the recent letter by Dr. R. W. L. Ward in the *Journal*, which says that "the profession has been too much occupied with its own remuneration and failed to recognize the responsibilities towards the bigger issues of national life." He advises the British Medical Association to define the conditions which we, as doctors, would plan as necessary for the benefit of the needs and health of the people in our social and economic systems. This would require a reconstitution of the functions and composition of the Medical Planning Commission, but it would be well worth it.

In your leading article on medicine in a changing world in the same issue you remark that "medicine cannot concern itself with the economic man, the political man, the religious man, or the legal man." Again you say that on such subjects as diet and nutrition doctors must speak in medical terms only, "uncontaminated with political partisanship or economic theorizing." Why so? Are there no honest men and women and sound knowledge in these and all callings of life? Indeed a good number of doctors, including myself, have practised such collaboration for years and found that many of these people would promote and advance the conditions doctors advocate. Our experience tells us that *if* the British Medical Association in drawing up the plans for the common health and welfare *ignores* the knowledge of the economists (who work out their financial aspect), or the help of the politicians (who would make honest laws to ensure them), or the lawyers (who would formulate these laws), or the men of religion (who practise and preach the lesson of the Sermon on the Mount), or, may I add, the cobbler who makes our shoes or the public who is to take our advice, then the Commission and the British Medical Association are again doomed to failure.

We shall be regarded as "shadow" doctors only and as a body of emasculated citizens, not full, free, equal, and good ones, unless we ask and call in any and all necessary technical advice and enlist the active personal support of one and all, and the good will, common sense, and co-operation of all good citizens, and translate our "prescription" into active scientific "treatment." Professional remuneration can be rightly left to the respect and the resources of the State and the community that provide the payment (and take our treatment) by mutual arrangement with the doctors and their allied and auxiliary colleagues, all of whose status and services would be enhanced in value.—I am, etc.,

Woking, Jan. 20. F. G. BUSHNELL, M.D.

SIR,—Your leading article on medicine in a changing world and the policy of the B.M.A. presumably expressed in this article should come as a shock to no one. The individual practitioner, by the very nature of his work, has the opportunity of becoming the most knowledgable of citizens, and by virtue of his scientific training is tempted to inquire into the political, economic, and other causes giving rise to the disease of mind and body affecting his patients. Knowledgable and scientifically minded citizens are potentially very dangerous to the peace of mind of Government Departments and centralized bureaux; they ask inconvenient questions at inconvenient times, and tend to start other members of the community thinking about the whys and wherefores of our present social disorder.

Your implied advice to the individual practitioner that he should be careful not to let Sir John Orr put dangerous ideas into his head, but instead be a busy little doctor getting on with his doctoring, so avoiding political and economic contamination, is most timely. So many members of the community already are under the impression that they are engaged in a war to defend the liberties of citizens against the tyrannies of power-drugged Governments and bureaux. That the cobbler must stick to his last and probably eschew any spare-time process of critical thought or inquiry inherent in good citizenship is, if disregarded in a totalitarian State, so apt to lead to liquidation.

Happily the individual practitioner has, in large part, been saved from these dangerous, citizenly activities by being allowed the barest minimum of spare time. He can now see that the close co-operation of the B.M.A. with the Ministry of Health, resulting in the increasingly onerous terms of service under the Ministry of Health and under central and local government bodies, has ensured his being kept safely tied to his stethoscope.

An editorial caveat against listening to the broadcasts of Mr. J. B. Priestley might guard the individual practitioner from this source of citizenly contamination.—I am, etc.,

Trentham, Jan. 27. R. CRICHTON PEATE.

SIR,—Surely you dismiss Dr. Maitland Radford too summarily. If we accept Sir John Orr's conclusions (and I take it they are not seriously questioned by the profession), then, since the nation will have to take action, we shall be expected to give some kind of a lead. Action will be political action, so we cannot keep politics out of it. But are we not citizens as well as doctors, and citizens with a special responsibility in this matter? Where but in our professional journals should we discuss ways and means to end this deplorable national failure? Of course there will be differences of opinion: of course our individual party politics will colour our arguments; but out of a free discussion some practical proposals may emerge upon which we can concentrate.—I am, etc.,

London, W.1, Jan. 30. C. E. WHEELER.

The Myotonic Pupil

SIR,—As a friend of the late W. J. Adie's my opinion on the direct issue which Mr. R. Foster Moore's letter (January 18, p. 99) raises would inevitably be too biased, and I refrain from expressing any. There are others with fuller knowledge of the circumstances and therefore better qualified to speak concerning Mr. Foster Moore's particular plaint. (It may, however, not be inappropriate to point out that Dr. F. M. R. Walshe, in his recent book *Diseases of the Nervous System*, speaks simply of the "myotonic pupil.") I have been interested to hear in conversation various and contrary opinions expressed on Mr. Foster Moore's letter. Might not the occasion afford an incentive to a discussion of more general interest—for example, on the historical significance of the value attached to academic eponymy, as an implement of success and power, in its broad relationship to various outstanding trends in our present-day Western civilization?

In a previous letter (October 23, 1937, p. 827) Mr. Foster Moore himself confessed that "claims for priority are apt to be undignified," but when we take into consideration the spirit of the times we should allow that there can be justification for such anxiety. In an age which measures "success," "cleverness," etc., on the basis of journalistic "scoops" those of us who might in other circumstances prefer the tranquillity of the study may have little choice than to acclaim our wares from the house-top as the only alternative to relative extinction. The significance of the modern value attached to "priority" in matters of "observation" is a very important aspect of competitive professionalism, if only because it has such a harmful influence on teaching.

It would be interesting to hear a discussion on this subject, and if Mr. Foster Moore's letter reveals—as it probably will—the impossibility of arriving at finality on such a small and particular issue as he raises, it will have served a useful purpose if it initiates some clarification of much more general considerations which its publication stimulates.—I am, etc.,

London, Jan. 27. BASIL GRAVES.

SIR,—It is clear that both your correspondents, Dr. Parkes Weber and Dr. Pappworth, have found published cases of abnormal pupil reactions which we may accept as examples of the condition under discussion; Dr. Pappworth refers to a case so early as 1813, and, as he very properly says, earlier cases may have been reported. No one, I fancy, would accept the publication of a single case of a condition as being sufficient to justify the application of the term "syndrome" to it; Dr. Pappworth does not state whether any of the published cases referred to by him are sufficiently comprehensive to justify such a term.

Had there been any inaccuracy in my letter it would be proper that it should be pointed out, and as such has not been done it may be taken that its accuracy is accepted, that in fact the characteristics and definition of the condition based on my series of cases were published in 1924—that is, a number of years before Adie published a single case of it. Dr. Pappworth says that my publication "has never received the recognition which it has deserved" because it was published in a specialized journal. Can he, however, suggest a more suitable medium for the publication of a group of cases of abnormal pupil reaction than the *Transactions of the Ophthalmological Society of the United Kingdom* and a textbook on medical ophthalmology? And, in any case, it was in the former *Transactions* that Adie published his cases six or seven years later.

I should like to say one further word on what Dr. Parkes Weber calls "wrangling on the question of priority" and Dr. Pappworth refers to as "haggling." Neither of these remarks seems to me in any way applicable to a letter which was a statement of facts which were left to speak for themselves; there was no mention of priority; it may, however, be noticed that Dr. Parkes Weber goes on "to claim priority" for a single case of his colleague and himself, and is sufficiently dogmatic to state that "this was the first demonstrated case" of the condition.—I am, etc.,

Salisbury, Feb. 3. R. FOSTER MOORE.

Medical Examination of Home Guard

SIR,—Dr. E. Wynne-Jones's letter (January 25, p. 137) was especially interesting in regard to the suggested appointment of a medical officer to each Home Guard battalion. This surely should be considered an absolute essential for any unit such as the Home Guard, who are undertaking active service and who, necessarily, should have not only a medical officer but also medical personnel to deal with casualties; also plans must be made in advance so that these casualties may be effectively treated and evacuated.

In the Edinburgh zone Home Guard medical officers have been attached to all the battalions since August, and they have had plenty of work to do, not in examining volunteers as Dr. Wynne-Jones has done, but in training personnel in first-aid work, forming battalion and company first-aid posts, looking after the various sanitation problems which arise, and making the necessary arrangements for the evacuation of casualties to the aid posts and therefrom. All these doctors have enrolled in the Home Guard as ordinary volunteers in the first instance and have then been posted to the various battalions as medical officers, being accorded the same status as that of a company commander. The senior medical officer, who is attached to zone headquarters and is responsible for the co-ordination of all the medical arrangements and collaboration with the military and civil authorities for the evacuation of casualties and other matters, is accorded the same status as a battalion commander. He attends all the zone headquarter conferences so that he can keep *au fait* with all that is going on and can give advice on all medical matters.

It is only by a scheme such as the above that casualties in the Home Guard can be effectively dealt with, and it seems extraordinary that this has not yet been apparently recognized and it has been left to individual Home Guard units to make their own medical arrangements without any help or co-ordination or even recognition of medical officers as such.—I am, etc.,

W. F. T. HAULTAIN,
Jan 27. Senior M.O., Edinburgh Zone, Home Guard.

The Scottish Ploughman's Dietary

SIR,—In the *Journal* of January 11 (p. 63) I mentioned Robert Burns's diet—that of the Scottish ploughman—as a matter of interest merely, not as illustrative of what the diet could do! It would be absurd to measure the value of the particular diet by the years of Burns's life (which, after all, is to be reckoned by what he was and achieved rather than by its length in years).

At the same time, it is known that, although Burns spent his life in hard toil and striving against poverty with its attendant evils, he did not suffer at any time from wrong or insufficient feeding. Energetic he was and of vigorous constitution, being of athletic build and powerful intellect. He was, however, always badly housed, and seemed compelled to live his short life in an environment bad in every respect. It was such adverse influence, along with occasional imprudent and indiscreet conduct—perhaps all too usual in those days—that predisposed him to an early death. Perhaps, too, Burns had to misguide him certain harmful peculiarities of temperament understandable in men of surpassing genius and brilliance, interested in everything and everybody but themselves and their own health and interests. At the last he developed a protracted illness which, from the clinical course it took, can only have been caused by a subacute infective endocarditis, not "rheumatism" or alcoholism, as has so often been said.

But, apart from all this, I believe that Dr. M. Newfield (January 18, p. 101) will agree with me that, if somewhat unappetizing, the ploughman's diet of oatmeal, broths in quantity, potatoes, milk, and the occasional herring, should constitute a sound basic diet for hungry days.—I am, etc.,

Bournemouth, Jan. 19. S. WATSON SMITH.

Perspiration and Flannel Clothing

SIR,—If Mr. R. Kennon (January 25, p. 137) will try the experiment of the flannel and the thermometer he will find *it does not work. The temperature remains obstinately* at 98.4°.—I am, etc.,

London, W.1, Jan. 31. C. K. VARTAN.

The Services

DEATHS IN THE SERVICES

Major-General Sir GEORGE BRADSHAW STANISTREET, K.B.E., C.B., C.M.G., late R.A.M.C., died at Bournemouth on January 26, aged 74. He was born on May 13, 1866, at Malahide, County Dublin, the son of Dr. Richard Stanistreet, and educated at Windermere College and at Trinity College, Dublin, where he graduated M.B., B.Ch., and B.A.O. in 1889, after taking the B.A. in 1887. He entered the Army as Surgeon Captain on July 28, 1891, became Lieutenant-Colonel on September 13, 1913, Colonel on December 26, 1917, Major-General in 1918, and retired on September 16, 1922. He served on the North-West Frontier of India in 1897–8, in the Tirah campaign, receiving the Frontier medal with two clasps, and throughout the war of 1914–18, when he filled the posts of Deputy Assistant Director-General, A.M.S., in 1913–17, Assistant Director-General in 1917–18, and Deputy Director-General in 1918–22. He received the C.M.G. in 1917, the C.B. in 1918, and the K.B.E. in 1922. He had been a member of the British Medical Association for over fifty years.
